ANTIGENS OF BOVINE SEMEN
AND THE INFLUENCE OF SPECIFIC RABBIT
ANTI-BULL-SEMEN SERUM ON
METABOLIC ACTIVITY OF BULL SPERMATOZOA

Summary. Bull semen is very strongly antigenic in rabbits. At least
twenty antigenic components were detected by micro-immunoelectro-
phoresis.

There was a drastic reduction in oxygen uptake, fructose utilization
and lactic acid production by bull spermatozoa when mixed with specific
antisemen serum. This decreased metabolic activity in the presence of
the antisemen was due to death of the spermatozoa as indicated by the
live–dead staining technique.

INTRODUCTION
Evidence has been accumulating in recent years that antibodies against semen
or washed spermatozoa can prevent fertilization, or may cause embryonic death
(Henle & Henle, 1940; Katsh, 1960; Menge, Stone, Tyler & Casida, 1962). The earliest observations that spermatozoa are antigenic were reported almost
simultaneously by three investigators—Landsteiner in 1899, and Metchnikoff
& Metalnikoff in 1900 (Katsh, 1960). The bulk of evidence in man (Weil &
Rodenburg, 1960; Weil, Kotsevalov & Wilson, 1956) and in rabbits (Weil &
Finkler, 1959; Weil, 1960) indicates that antigenic material is taken up by the
spermatozoa from the seminal plasma. There is also evidence that spermatozoa
do possess antigenic properties originating in the spermatozoa themselves
(Freund, Thompson & Lipton, 1955) and spermatozoa and seminal plasma are known to share common antigenic constituents (Pernot & Szumowski,
1958). Rao & Sadri (1959, 1960) have found at least sixteen antigens in buffalo
 seminal plasma and seven in spermatozoa, of which four are common to both.
In the bovine, evidence has been presented by Gordon & Hunter (1961) that
bull spermatozoa contain at least seven antigens of which at least one is
spermatozoa-specific. A report by Hunter & Hafs (1964) suggesting three
spermatozoa-specific antigens in the semen of cattle appeared when this paper
was being prepared for publication. Hathaway & Hartree (1963) have reported
four antigens in ram sperm extracts and the same four antigens in ram seminal
plasma. Metz, Schuel & Bischoff (1964) have observed that spermatozoa pretreated with univalent antibody have markedly reduced fertilizing capacity. Thus it appears that species differences exist in the antigenicity of spermatozoa, and that specific antisera somehow reduce the fertilizing capacity of spermatozoa. In view of these observations a series of experiments were undertaken to determine (a) the antigenicity of bull semen in female rabbits and (b) the change in metabolic activity of bull spermatozoa when mixed with rabbit anti-bull semen serum.

MATERIALS AND METHODS

Immune sera

All the semen samples for immunization of rabbits were collected from one Holstein-Friesian bull by means of an artificial vagina and were frozen at 

\[ -20^\circ\text{C} \]

soon after collection. Normal sera (ns) were obtained from four female rabbits (of mixed breeds) prior to immunization and were used as control samples. Each rabbit received injections of 1 ml thawed whole semen and antibiotic mixture (penicillin G : 10,000 units and dihydrostreptomycin : 4000 mg). A fifth doe was injected with antibiotic mixture alone (antibiotic control).

Rabbits were bled by heart puncture 8 days after the last injection, and the sera collected were frozen at 

\[ -20^\circ\text{C} \] .

Analysis of immune precipitates

Antigenic components of bull semen as detected by rabbit antisera were characterized by a modification of the immunoelectrophoresis technique of Grabar & Williams (1955) and Scheidegger (1955). Slides (2 in. × 3 in.) were prepared using agar gel containing 1 g Ionagar 2, and 1 ml of 1 % merthiolate solution in 100 ml B-2 Spinco Barbital buffer (ionic strength 0-05). Freshly collected whole semen was frozen at 

\[ -20^\circ\text{C} \] and thawed at room temperature alternately three times in order to rupture the cells, immediately prior to electrophoresis, and 0-002 ml of the prepared semen was pipetted into each of the two holes on a slide. Electrophoresis was performed for 3 hr at 14 mA constant current/slide with voltage ranging between 100 and 110 V. Immediately after electrophoresis freshly thawed antisemen serum was pipetted into a trench cut in the middle of the slide between the two holes and was allowed to diffuse at refrigerator temperature (4°C). Normal sera and antisera were used undiluted and without heat inactivation throughout this study. After 2 days in the refrigerator the gels were set in distilled water for another 2 days, air dried, stained with amidob black 10 and photographed.
Metabolic studies

Bull semen of good initial motility was used and in all cases the ejaculates contained approximately 1.3 x 10^9 spermatozoa/ml. Six replications of each of the following treatments were tested:

1. 0.4 ml semen + 0.8 ml saline.
2. 0.4 ml semen + 0.4 ml saline + 0.4 ml NS.
3. 0.4 ml semen + 0.4 ml saline + 0.4 ml rabbit anti-bull semen serum.
4. 0.4 ml semen + 0.4 ml saline fructose + 0.4 ml NS.
5. 0.4 ml semen + 0.4 ml saline fructose + 0.4 ml rabbit anti-bull semen serum.

The uptake of oxygen was measured by the direct Warburg technique using air as the gas phase (Umbreit, Burris & Stauffer, 1957); fructose was measured by Mann's modification (1946) of the method of Roe (1934); and lactic acid was determined by the method of Barker & Summerson (1941). Analysis of variance of the data obtained was used for interpretation of the results.

RESULTS

Immunological studies

In tests using micro-agar immuno-electrophoresis, no detectable antibody was found in the serum of a control rabbit immunized with antibiotic mixture, whereas at least twenty antigen–antibody precipitin systems were demonstrable in serum from rabbits immunized with bull semen + antibiotic mixture (Plate 1).

† All motile sperm in this group in one flask.

Metabolic studies

The results show a highly significant (P < 0.01) reduction in the amount of oxygen consumed, and of lactic acid produced by the spermatozoa in presence of antisemen compared to normal serum controls during the period of 4 hr (Table 1). The two values of the saline control were lower than the serum controls but higher than the antisemen-treated samples, showing that total metabolic activity of spermatozoa is greater in the presence of rabbit normal serum and saline or saline fructose than when mixed with saline alone.
At the end of 4-hr incubation, samples were tested for the percentage of motile spermatozoa, rate of motility and percentage of live spermatozoa. Averages of observations for each group are given in Table 1.

The results show that the percentage of motile spermatozoa, as well as the rate of motility, was drastically reduced on treatment with rabbit anti-bull semen serum. This was further substantiated by eosin staining by the technique of Lasley, Easley & McKenzie (1942). The few cells which were alive (in only two of the six flasks containing antisemen-treated samples) may have been in the flask sidearm and thus may not come in contact with the antisemen serum.

A separate test run (Table 2) was made with equal volumes of antisemen and semen, ns and semen, and saline and semen. No live spermatozoa (as detected by eosin stain) were observed in the antisemen-treated semen samples at the end of 38 min after mixing. Sperm cells in the presence of ns or saline showed no such increased mortality, even at the end of 1 hr (total period of test).

**DISCUSSION**

The results of this study show that specific anti-bull semen serum significantly reduced the metabolic activity of bovine spermatozoa when the two were mixed. This decrease in the total metabolic activity of all cells in an antisemen-treated sample was due to death of the cells, apparently caused by a strong agglutination reaction between spermatozoa and specific antibodies. Whether the agglutination was due to antibodies reacting specifically with the antigens of the spermatozoa or with the antigens absorbed by the spermatozoa from the seminal plasma was not determined. A pronounced agglutination reaction was, however, clearly visible under the microscope; spermatozoa became quiescent within seconds after making contact with antisemen serum. Neither the normal nor immune sera were heat-inactivated, so that any effects of complement would be expected to be the same for all sera. The toxic effect of normal serum on spermatozoa which has been observed by a number of workers (e.g. Chang, 1947; Edwards, 1960; Spooner, 1964) was not evident, and was most probably obscured by the large numbers of spermatozoa present relative to serum concentration.
The results of immunoelectrophoresis of bull semen. The horizontal trough was filled with rabbit anti-bull semen serum. A. Photograph of the complete preparation stained with amido black. B. The same preparation in which the precipitin arcs are traced after projection on paper by means of a magnifier.
The normal sera of female rabbits as compared to saline controls did not reduce the activity of bull spermatozoa; motility was higher at the end of the 4-hr incubation period in those samples treated with saline+ns than in those treated with saline alone (Table 1). This difference in physical activity (nearly the same proportion of the cells were alive at the end of the period) could explain the differences observed in utilization of oxygen. There was also an increased fructose utilization, lactate accumulation and higher final motility present in the saline+ns-treated samples as compared to the saline fructose+ns-treated samples. The stimulatory effect of ns and the somewhatless stimulatory effect of fructose in relation to it, were not investigated further.

Immunologically, bull semen is very strongly antigenic in female rabbits; no adjuvant or prolonged series of immunizations was required to get a titre of antibodies four times higher than was necessary for detectable precipitation reactions.
