Experiments were designed to test the hypotheses that (1) follistatin gene expression in granulosa cells is regulated during follicular growth, and (2) that alteration of follistatin mRNA concentration can be hormonally induced in primary cultures of porcine granulosa cells. RNA isolated from granulosa cells from small (1–3 mm diameter), medium (3–5 mm) and large (> 5 mm) follicles of prepubertal and postpubertal sows was analysed by hybridization to a porcine follistatin cDNA probe. Amounts of follistatin mRNA increased with follicular diameter, but no differences in follicular follistatin mRNA were detected between prepubertal and postpubertal sows. Treatment of cultured porcine granulosa cells with FSH or LH for 20 h stimulated follistatin mRNA concentration by a factor of two (100 ng FSH ml⁻¹) and a factor of 1.5 (10 ng LH ml⁻¹), respectively, over untreated controls. Treatment of cultured granulosa cells with 200 ng FSH ml⁻¹, 200 ng LH ml⁻¹, 10 μmol dibutyryl cAMP l⁻¹, 30 μmol forskolin l⁻¹ and 100 ng cholera toxin ml⁻¹ stimulated follistatin mRNA accumulation in granulosa cells by factors of 4.9, 3.7, 1.6, 13.7 and 3.5, respectively, compared with control cultures. Stimulation of follistatin mRNA accumulation in cultured granulosa cells by dibutyryl cAMP (30, 100 and 300 μmol l⁻¹) and forskolin (3, 10 and 100 μmol l⁻¹) was dose dependent. FSH and forskolin induced time-dependent increases in follistatin mRNA concentration in cultured granulosa cells, with maximal induction occurring 72 h after treatment (a factor of 4.5 for FSH and 15.5 for forskolin). These results demonstrate that (1) increased follistatin mRNA in granulosa cells is associated with increased follicular diameter, (2) increased follistatin mRNA in cultured porcine granulosa cells can be induced by gonadotrophins, and (3) the gonadotrophin-induced increase in follistatin mRNA accumulation in cultured granulosa cells can be mimicked by agents that increase intracellular cAMP concentrations.

Introduction

Follistatin is an ovarian glycoprotein that can suppress FSH release from anterior pituitary cells in vitro (Robertson et al., 1987; Ueno et al., 1987). Although follistatin was initially isolated from bovine and porcine follicular fluids, mRNA for follistatin is found in many tissues, including the ovary, kidney, brain (Shimasaki et al., 1989), decidual tissue (Kaiser et al., 1990), testis, adrenal, thymus, pancreas, gut, heart, uterus, skeletal muscle, lung (Michel et al., 1990) and pituitary (Gospodarowicz and Lau, 1989; Michel et al., 1990), indicating that follistatin activity may not be restricted to the reproductive system. Follistatin is structurally unrelated to inhibins and activins (Esch et al., 1987; Shimasaki et al., 1988; Shimasaki et al., 1989). Nevertheless, a relationship among these putative ovarian FSH-regulatory peptides was suggested by the discovery that follistatin binds activin in the ovary (Nakamura et al., 1990) and pituitary (Kogawa et al., 1991). Follistatin was subsequently demonstrated to bind both activin and inhibin by associating with the common β subunit of these proteins (Shimonaka et al., 1991).

In addition to effects on the pituitary and possible autocrine effects on granulosa cell physiology (Shukovski et al., 1991), follistatin may function as a modulator or inhibitor of activin (DePaolo et al., 1991), which stimulates FSH release from cultured pituitary cells (Ling et al., 1986) and has effects upon differentiation in an erythroid cell line (Eto et al., 1987; Brommeyer et al., 1988), in P19 teratoma cells (Schubert et al., 1990), and in an embryonal carcinoma cell line (Van den Eijnden-Van Raaij et al., 1991). This contention suggests that follistatin and activin may have a regulatory role in differentiative processes in a variety of cell types (DePaolo et al., 1991). Follistatin mRNA is most abundant in the granulosa cells of growing secondary and tertiary follicles from immature rat.
ovaries (Shimasaki et al., 1989), suggesting that follistatin may be differentially expressed during follicular growth. In bovine ovaries, follistatin transcripts are found in granulosa cells from all antral follicles, reaching highest concentration in preovulatory follicles (Shukovski et al., 1992). The differential expression of follistatin mRNA in granulosa cells of growing follicles suggests that factors involved in follicular development may regulate follistatin gene expression. Furthermore, exogenous gonadotrophins upregulate ovarian follistatin mRNA concentration in vivo (Shimasaki et al., 1989). This finding implies that expression of the follistatin gene may be hormonally regulated.

The purpose of this study was to determine whether steady-state follistatin mRNA concentrations change during growth of antral follicles in pigs. In addition, primary cultures of porcine granulosa cells were used to investigate the regulation of follistatin gene expression by gonadotrophins and cyclic AMP (cAMP).

Materials and Methods

Isolation of porcine cDNA by reverse transcription PCR

Oligonucleotide primers were designed to amplify a region of the porcine cDNA sequence from the ATG initiation codon to nucleotide 1023 based on the porcine cDNA sequence published by Esch et al. (1987), and incorporating a BamHI restriction enzyme recognition site at each end to facilitate cloning. Primer sequences were located in different exons to allow discrimination between amplification of cDNA and any contaminating genomic DNA. The following oligonucleotide primers were made on an Applied Biosystems synthesizer: 5′GGATCCATGTGGTCCGTCCAAGCAC3′ and 5′GGATCTTCAGTACGTCGGTTCTC3′. Total RNA was isolated from 2 g of ovarian tissue from an adult sow by the guanidinium isothiocyanate—cesium chloride method (Kingston, 1989).

Total RNA was reverse transcribed (RT) using the following reaction conditions in 25 µl at 42°C for 1 h: 50 µg total RNA, 0.5 µg oligo dT15 primer, 10 mmol dithiothreitol 1−1 (Sigma Chemical Co., St Louis, MO), 1 mmol MgCl2 1−1 each of dATP, dCTP, dGTP and dTTP (Pharmacia, Baie d'Urte, Quebec), 8000 U RNAsin ribonuclease inhibitor (Fisher/ Promega, Nepean), 4 mmol sodium pyrophosphate 1−1, 50 mmol Tris-HCl 1−1, pH 8.3, 75 mmol KCl 1−1, 10 mmol MgCl2 1−1, 0.5 mmol spermidine 1−1 (Sigma Chemical Co.) and 20 U AMV reverse transcriptase (Fisher/Promega). Five microlitres of this reaction was added to a PCR mixture in 50 µl as follows: 0.2 mmol l−1 each of dATP, dCTP, dGTP and dTTP, 10 mmol Tris—HCl 1−1, pH 8.3, 50 mmol KCl 1−1, 1.5 mmol MgCl2 1−1, 0.01% (w/v) gelatin, 2.5 µA Taq DNA polymerase (Perkin Elmer Cetus, Norwalk), 50 pmol each primer. Twenty-five PCR cycles were conducted at 94°C for 1.5 min, 56°C for 2 min, then 72°C for 2 min, extending the 72°C period for 15 s each cycle.

The RT—PCR product was ligated into the BamHI site of the plasmid pGEM3ZR (−) (Fisher/Promega). The identity of the cloned cDNA was confirmed by DNA sequencing and restriction endonuclease mapping using internal BglII and PstI recognition sites. The cloned follistatin cDNA fragment hybridized to a single 2.5 kb species of RNA in porcine granulosa cells, in agreement with a previous report of follistatin mRNA in porcine ovarian tissue (Shimasaki et al., 1988).

Porcine granulosa cell culture

Granulosa cell culture medium consisted of minimum essential medium (MEM) containing 0.1 mmol MEM non-essential amino acids 1−1, 25 mmol Hepes 1−1, 26 mmol NaHCO3 1−1, 0.06 g benzylpenicillin 1−1, 0.1 g streptomycin sulfate 1−1 (all from Gibco/BRL, Burlington), and 1 mmol NaOH 1−1 (Sigma Chemical Co.). Ovaries were collected from immature pigs at a local abattoir and transported to the laboratory in sterile, ice-cold saline containing 0.06 g benzylpenicillin 1−1 and 0.1 g streptomycin sulfate 1−1. Folicular fluid was aspirated from 3–5 mm diameter follicles using a 21 gauge needle and syringe. Follricular membranes were dissected from the ovaries using fine forceps, and granulosa cells were scraped from these membranes with a scalpel. Cells were dispersed by trituration with a 20 µl syringe and then filtered through sterile steel mesh (0.14 mm mesh; Sigma Chemical Co.). Cells were washed twice in culture medium, counted and plated at a density of 1×10⁶ cells ml−1 in Falcon six-well tissue culture plates (Becton Dickinson, Lincoln Park, NJ) in culture medium containing 10% heat-inactivated fetal bovine serum. After incubation for 48 h in 95% humidified air with 5% CO₂ at 37°C, medium was replaced with culture medium without serum. Cells were incubated for a further 48 h, after which time the medium was changed and treatments added. After the treatment period, medium was removed and stored at −20°C.

RNA isolation

Cultured granulosa cells were lysed in 4 mol guanidinium isothiocyanate 1−1, 20 mmol sodium acetate 1−1, 0.2 mmol dithiothreitol 1−1, 0.5% N-lauryl sarcosine (Sigma Chemical Co.), then triturated through a 21 gauge needle, layered onto a gradient of 5.7 mol caesium chloride 1−1, and centrifuged at 174 000 g for 20 h at 22°C. The RNA pellet was dissolved in 10 mmol Tris—Cl 1−1, pH 7.4, 5 mmol EDTA 1−1, 1% sodium dodecyl sulfate (SDS), precipitated twice with 0.1 volume of 3 mol sodium acetate 1−1 and two volumes of absolute ethanol, dried under vacuum, then dissolved in diethylpyrocarbonate-treated distilled water and stored at −70°C. Concentration of nucleic acid was determined by measurement of absorbance at 260 nm.

Northern and slot blot hybridizations

For northern blot analysis, RNA was separated on 1% agarose formaldehyde gels, then stained with ethidium bromide (Sambrook et al., 1989). The RNA was transferred to a nylon membrane (Hybond-N: Amersham, Oakville, Ontario) by capillary transfer overnight in 10 × SSC (1 × SSC = 150 mmol NaCl 1−1, 15 mmol trisodium citrate 1−1, pH 7.0).

For slot blot analyses, 6 µg total RNA in 50 µl water was heated to 65°C for 10 min in 150 µl denaturing solution consisting of 98 µl deionized formamide, 32 µl 37% formaldehyde and 20 µl 10 × MOPS buffer (0.2 mol 3-[N-morpholino] propanesulfonic acid 1−1, 0.5 mol sodium acetate 1−1,
pH 7.0. 0.01 mol sodium EDTA L−1). An equal volume of ice-cold 20 × SSC was added to the samples, which were then applied to a nylon membrane using a slot blot manifold (Bio-Rad, Mississauga).

RNA was cross-linked to nylon membranes with UV light using a UV Stratalinker 2400 (Stratagene, La Jolla, CA). The hybridization procedure consisted of rinsing the membrane in 6 × SSPE (1 × SSPE = 180 mmol sodium chloride L−1, 10 mmol sodium phosphate L−1, 1 mmol EDTA L−1, pH 7.4), then prehybridizing for 1 h at 65°C in hybridization solution (5 × SSPE, 5 × Denhardt’s solution: 0.5% SDS, 10% dextran sulfate, 200 µg denatured salmon sperm DNA mL−1, Sigma Chemical Co.). The membrane was then incubated at 65°C overnight in hybridization solution containing denatured [32P]-labelled follistatin cDNA or human γ actin cDNA (labelled to a specific activity of between 1.5 and 3.0 d.p.m. µg-1 DNA), which was used as an internal control for RNA loading. Membranes were washed twice with 2 × SSPE 0.1% SDS at room temperature and twice with 0.1 × SSPE, 0.1% SDS at 65°C for 15 min per wash. Blots were subjected to autoradiography using Kodak XAR-5 film. Autoradiographs were scanned with an LKB Ultra-Scan laser densitometer (Pharmacia, Baie D’Urfé, Quebec). Slot blot data were expressed as arbitrary densitometric units for follistatin mRNA relative to γ actin mRNA.

Progesterone radioimmunoassay

Cell culture medium was assayed for progesterone content without prior extraction. Progesterone concentrations were determined by liquid-phase radioimmunoassay (Rajkumar et al., 1985) using a rabbit antiserum against 4-pregnen-11α-ol-3, 20-dione hemisuccinate—BSA (NC Rawlings, Department of Veterinary Physiological Sciences, University of Saskatchewan, Saskatoon), and progesterone-11α-glucuronide-[125]I]iodotyramine as tracer (Amersham). Bound ligand was precipitated using 17% polyethylene glycol 8000 (Sigma Chemical Co.).

Statistical analyses

Results of progesterone assays were analysed by one-way analysis of variance. Differences between means were determined using Duncan’s multiple range test (Steel and Torrie, 1960).

Hormones and chemicals

Cyclic AMP, forskolin and cholera toxin were purchased from Sigma Chemical Co., FSH (NIADDK-oFSH-17) and LH (NIADDK-oLH-25) were a gift from NIDDK.

Results

Follistatin gene expression in granulosa cells from small, medium and large follicles

To determine whether follistatin gene expression increases during growth of antral follicles, we measured the abundance of follistatin mRNA in granulosa cells isolated from small (1–3 mm), medium (3–5 mm) and large (> 5 mm) follicles collected from sows at an abattoir. Slot blot analysis of total cellular RNA collected from granulosa cells from pooled small, medium and large follicles demonstrated that the steady-state concentrations of follistatin mRNA increased with follicular diameter in both prepubertal and postpubertal sows (Fig. 1).

Regulation of follistatin gene expression in cultured granulosa cells by gonadotrophins

The effects of gonadotrophins on follistatin gene expression were investigated in serum-free cell culture. Steady-state concentrations of follistatin mRNA increased in granulosa cells treated with 100 ng ovine FSH (o-FSH) mL−1 for 20 h (Fig. 2a). Both FSH and LH caused dose-dependent increases in follistatin mRNA accumulation in granulosa cells, as determined by laser densitometry of slot blots hybridized to follistatin cDNA probe (Fig. 2a). The viability and appropriate biological function of the cells was demonstrated by the increase in progesterone secretion into the culture medium in response to FSH and LH (Fig. 2b).

Regulation of follistatin gene expression by cAMP, forskolin and cholera toxin

Treatment of granulosa cells with 10 µmol dibutyryl cAMP L−1, 30 µmol forskolin L−1, 100 ng cholera toxin mL−1, 200 ng FSH mL−1 or 200 ng LH mL−1 for 20 h resulted in increases in follistatin mRNA accumulation by factors of 1.6, 13.7, 3.5, 4.9, and 3.7, respectively (Fig. 3). Dose-dependent stimulation of follistatin mRNA accumulation by dibutyryl cAMP (30, 100 and 300 µmol L−1) and forskolin (3, 10 and 30 µmol L−1) was demonstrated by northern blot analysis of granulosa cell RNA,

Fig. 1. Follistatin mRNA content in granulosa cells of growing antral follicles. Total RNA was isolated from granulosa cells of small (1–3 mm), medium (3–5 mm), and large (> 5 mm) antral follicles from prepubertal (□) and postpubertal (□□) pigs. RNA from pooled granulosa cells of each size class was analysed by slot blot hybridization to [32P]-labelled follistatin and γ actin cDNA probes. Data are presented as arbitrary densitometric units for follistatin relative to γ actin mRNA, adjusted to a value of 1.0 for the samples from 1 to 3 mm follicles of prepubertal pigs.
using 15 µg of total cellular RNA per lane (Fig. 4a). This experiment was repeated and analysed by slot blot hybridization to follistatin and γ actin cDNA probes. Dibutyryl cAMP and forskolin increased follistatin mRNA accumulation in granulosa cells by a factor of 5.2 (cAMP, 300 µmol l⁻¹) and 4.1 (forskolin, 30 µmol l⁻¹) compared with untreated cells (Fig. 4b). The magnitude of induction of follistatin mRNA expression in response to cAMP and forskolin varied between experiments, reflecting possible differences in the populations of cells isolated for each experiment.

**Time-dependent regulation of follistatin gene expression by FSH and forskolin**

The time-course of stimulation of follistatin gene expression by FSH and forskolin in cultured granulosa cells was examined. Cells treated with 100 ng FSH ml⁻¹, 10 µmol forskolin l⁻¹ or culture medium (MEM) (negative control) were harvested for RNA isolation at 0, 12, 24, 48 and 72 h after the addition of treatments (Fig. 5a). Accumulation of follistatin mRNA induced by FSH increased by factors of 2.7 (12 h), 3.8 (24 h), 3.4 (48 h) and 4.5 (72 h) compared with the mean negative control at zero time. Similarly, forskolin induced follistatin mRNA accumulation by factors of 3.4 (12 h), 3.6 (24 h), 7.9 (48 h) and 15.5 (72 h) compared with control values at zero time. The induction of follistatin gene expression over 72 h was accompanied by a corresponding increase in progesterone accumulation in the culture medium in response to both FSH and forskolin (Fig. 5b).

**Discussion**

Using a full-length porcine follistatin cDNA probe generated by RT-PCR of ovarian RNA, we showed that follistatin mRNA concentrations in granulosa cells increased during growth of antral follicles in the pig. Changes in follistatin gene expression during follicular development have been demonstrated in rat ovaries by *in situ* hybridization (Nakatani et al., 1991). These authors detected a strong signal for follistatin mRNA in all antral follicles, except those undergoing atresia. The present study shows that follistatin mRNA is present in granulosa cells of porcine antral follicles, and also demonstrates that the abundance of follistatin mRNA increases with follicular diameter. Similarly, Shukovsky et al. (1992) recently reported that steady-state concentrations of follistatin mRNA increase with follicular diameter in granulosa cells from bovine antral follicles, reaching a maximum in preovulatory follicles. This finding suggests that follistatin expression may be associated with the process of granulosa cell differentiation or proliferation during follicular maturation *in vivo*. 
In this study, we also demonstrated the regulation of follistatin gene expression in cultured porcine granulosa cells in response to gonadotrophins and agents that stimulate intracellular cAMP production. Using a primary porcine granulosa cell model, we found that FSH stimulated follistatin mRNA accumulation in a dose- and time-dependent manner. The cells used for primary culture were isolated from follicles with a diameter of 3–5 mm, to reduce the possible variability associated with differences in the stage of granulosa cell differentiation at the start of culture (Channing, 1970). The time course of stimulation of follistatin mRNA by FSH indicated that maximal stimulation occurs after chronic exposure to FSH. Prolonged exposure to FSH also resulted in increased progesterone secretion, which is evidence of granulosa cell differentiation. This suggests that granulosa cell differentiation is associated with increased expression of follistatin mRNA. Although a causative role for follistatin in this process has not been unequivocally established, the studies of Shukovsky et al. (1991) suggest that follistatin can induce luteinization of bovine granulosa cells in vitro.

Effects of FSH on follistatin mRNA accumulation have not previously been demonstrated in cultured porcine granulosa cells. However, in primary cultures of bovine granulosa cells, the secretion of follistatin increased in response to bovine FSH by a factor of 2–3 compared with untreated controls (Klein et al., 1991). In addition, the effect of FSH on follistatin secretion was dose dependent: maximal stimulation occurred at a dose of 20 ng ml⁻¹ (Klein et al., 1991). Using an activin-binding assay, Saito et al. (1991) showed that equine FSH stimulated follistatin secretion by rat granulosa cells in a dose-dependent manner after 72 h incubation, with a maximal effective dose of 30 ng ml⁻¹. Our results demonstrate that in cultured porcine granulosa cells, gonadotrophins exert their effect by stimulating follistatin mRNA accumulation, which could be accounted for either by increased transcription or increased mRNA stability. This finding does not exclude a concomitant effect of gonadotrophins on follistatin translation.
LH also caused a dose-dependent increase in follistatin mRNA accumulation. Although the effects of LH on follistatin mRNA concentration in porcine granulosa cells have not previously been reported, these results are inconsistent with two studies in which LH had no effect on secretion of follistatin in bovine (Klein et al., 1991) or rat (Saito et al., 1991) granulosa cells. This disparity may be the result of differences in the model systems. For instance, granulosa cells from immature, oestrogen-primed rats do not respond to LH unless previously stimulated with FSH to induce expression of LH receptors (Hsueh et al., 1984). In contrast, the primary cultures of porcine granulosa cells used in the present experiments secreted large amounts of progesterone in response to LH alone. Since both FSH and LH are considered to act principally by activation of adenyl cyclase and stimulation of intracellular cAMP (Marsh, 1976), either gonadotrophin should stimulate cAMP-dependent follistatin gene expression, provided that the appropriate receptors are present.

The stimulation of follistatin mRNA concentration by gonadotrophins resulted in an increase between 1.5 and 5 times that of control in different experiments. Similarly, induction of follistatin gene expression by forskolin varied between 4- and 13.7-fold increases. The variability in responses to the same conditions between experiments may be a result of variability in cell populations. Since freshly isolated cells were used for each experiment, differences in age and genetic background of the donor pigs could contribute to the variable follistatin gene induction. We found that within a cell culture experiment, the stimulation of follistatin gene induction by a particular drug is very consistent.

Many of the effects of FSH and LH on the differentiation of cultured granulosa cells can be mimicked by treating the cells with agents that increase intracellular cAMP concentration (Knecht et al., 1983). We tested the hypothesis that follistatin gene expression is regulated by cAMP-dependent mechanisms. Forskolin, cholera toxin and the cAMP analogue dibutyryl cAMP all induced follistatin mRNA accumulation in porcine granulosa cells. Moreover, both dibutyryl cAMP and forskolin induced dose-dependent stimulation of follistatin mRNA accumulation. In addition, forskolin induced a time-dependent stimulation of follistatin mRNA accumulation. Klein et al. (1991) showed that 8-bromo-cAMP stimulated follistatin secretion from cultured bovine granulosa cells. The results of the present investigation support the hypothesis that cAMP-dependent mechanisms stimulate follistatin expression at least partly at the pre-translational level. We also showed that phorbol 12-myristate 13-acetate, a protein kinase C activator, and epidermal growth factor acutely stimulate follistatin mRNA expression in cultured granulosa cells (Lindell et al., 1993), suggesting that the follistatin gene may be regulated by multiple pathways in granulosa cells.

The role of follistatin in reproduction is still unclear. Although it was isolated by virtue of its inhibin-like activity on pituitary cells, its role as a negative regulator of FSH secretion in vivo has not been conclusively demonstrated. There is some evidence that follistatin may downregulate FSH secretion in vivo, since injection of rats with native or recombinant porcine follistatin reduces circulating FSH concentrations (Inouye et al., 1991). However, the link between follistatin synthesis and fluctuations in FSH concentrations during the oestrous cycle has not been rigorously established. Stimulation of ovarian follistatin mRNA concentration by gonadotrophins in vivo has been observed in rats (Shimasaki et al., 1989) and has been confirmed in our laboratory (data not shown). The present study shows that gonadotrophins also upregulate follistatin gene expression in cultured porcine granulosa cells. A primary effect of gonadotrophins is to induce differentiation of cultured granulosa cells, suggesting that follistatin gene expression increases as the cells differentiate. In fact, our studies showed an accumulation of follistatin mRNA up to 72 h after treatment, accompanied by increased progesterone accumulation in the culture medium. It is possible that the progesterone produced by the cultured granulosa cells under the influence of cAMP may be acting as an autocrine regulator of follistatin gene expression. Our finding that follistatin mRNA concentration increases with follicular diameter in pigs suggests that follistatin gene expression may also be upregulated during granulosa cell differentiation in vivo.

We conclude that gonadotrophins and cAMP can stimulate follistatin mRNA accumulation in cultured porcine granulosa cells, which indicates that increased follistatin gene expression may be associated with granulosa cell differentiation in vitro.

The authors would like to thank the National Hormone and Pituitary Program, NIDDK, for generously providing us with LH and FSH used in this study. They also thank Y. Y. Shi and A. Koziel-Andrzejewska for their assistance with granulosa cell culture, and P. Ward for synthesizing the oligonucleotides. Experiments were funded by MRC operating grant no. MT11018 and NSERC strategic grant no. T01265 to B. D. Murphy. C. E. Lindell was supported by a fellowship from the Medical Research Council of Canada.
