Abstract

The enzyme 20 α -hydroxysteroid dehydrogenase (20 α -HSD) catalyzes the conversion of progesterone to its inactive form, 20 α -hydroxyprogesterone. This enzyme plays a critical role in the regulation of luteal function in female mammals. In this study, we conducted the characterization and functional analyses of bovine 20 α -HSD from placental and ovarian tissues. The nucleotide sequence of bovine 20 α -HSD showed significant homology to that of goats (96%), humans (84%), rabbits (83%), and mice (81%). The mRNA levels increased gradually throughout the estrous cycle, the highest being in the corpus luteum (CL) 1 stage. Northern blot analysis revealed a 1.2 kb mRNA in the bovine placental and ovarian tissues. An antibody specific to bovine 20 α -HSD was generated in a rabbit immunized with the purified, recombinant protein. Recombinant 20 α -HSD protein produced in mammalian cells had a molecular weight of ~37 kDa. Bacterially expressed bovine 20 α -HSD protein showed enzymatic activity. The expression pattern of the 20 α -HSD protein in the pre-parturition placenta and the CL1 stage of the estrous cycle was similar to the level of 20 α -HSD mRNA expression. Immunohistochemical analysis also revealed that bovine 20 α -HSD protein was intensively localized in the large luteal cells during the late estrous cycle.

Reproduction (2011) **142** 723–731

Introduction

In all mammalian species, progesterone is essential in the preparation for and maintenance of pregnancy, if it occurs. Progesterone primes the endometrium for possible implantation and inhibits uterine contraction until birth. Aldo-keto reductases (AKRs) belong to a superfamily of NADPH-dependent reductases that act on a wide range of substrates, including simple carbohydrates, steroid hormones, and endogenous prostaglandins (Jez *et al.* 1997). The 20 α -hydroxysteroid dehydrogenase (20 α -HSD) is a member of AKR family (Liu *et al.* 2007).

The 20 α -HSD enzyme predominantly converts progesterone into its biologically inactive form, 20 α -hydroxyprogesterone (20 α -OHP) and plays a crucial role in the termination of pregnancy and the initiation of parturition (Seong *et al.* 2002). Accordingly, 20 α -HSD in the placenta may be involved in reducing the cytotoxic

effects of progesterone in the developing fetus. The biological functions of 20 α -HSD have been intensively studied in rats and mice because the enzyme plays a pivotal role in rodent reproduction (Albarracin *et al.* 1994, Dufort *et al.* 1996, Akinola *et al.* 1997, Bryndova *et al.* 2006).

The potential role of 20 α -HSD in the corpus luteum (CL) during pregnancy has been determined by cloning the mouse 20 α -HSD cDNA (Ishida *et al.* 1999). 20 α -HSD is expressed in the CL of rats and mice and has been shown to be involved in the process of functional luteolysis during the rodent estrous cycle (Miura *et al.* 1994, Seong *et al.* 2002). In rodents, 20 α -HSD activity is suppressed in the CL by prolactin or placental lactogens during pregnancy and abruptly increases before parturition, which is associated with a decrease in progesterone levels and a reciprocal increase in 20 α -OHP levels (Akinola *et al.* 1997). Notably, 20 α -HSD has also been found in the placenta of rats (Shiota *et al.* 1993), mice

(Ishida *et al.* 1999), goats (Jayasekara *et al.* 2004), and humans (Stickler *et al.* 1981, Zhang *et al.* 2000, Nakajima *et al.* 2003).

cDNA clones encoding bovine testicular 20 α -HSD have been isolated from a bovine testicular λ gt11 library using polyclonal antibodies against 20 α -HSD and DNA probe hybridization (Warren *et al.* 1993). However, the nucleotide and deduced amino acid sequences of bovine 20 α -HSD showed very low similarity to goat 20 α -HSD (43%; Jayasekara *et al.* 2004). Bovine testicular 20 α -HSD has weak activity and differs markedly from the ovarian enzyme with respect to the amino acid sequence.

In this study, we determined the sequence of the entire bovine 20 α -HSD cDNA, analyzed the sequence homology, and generated a specific antibody against bovine 20 α -HSD using the recombinant protein produced in the *Escherichia coli* (*E. coli*) system. We then conducted northern blot analysis, expressed the recombinant protein in Chinese hamster ovary (CHO) cells, and performed western blot and immunohistochemical analyses.

Results

Determination of the bovine 20 α -HSD cDNA sequence

Using partial cDNA cloning, a 572 bp fragment was amplified from bovine complete placentome tissue before parturition. Subsequently, two fragments of 350

and 300 bp were obtained using 3'- and 5'-RACE respectively. The full nucleotide sequence of the cloned bovine 20 α -HSD cDNA was 1127 bp, including 32 bp in the 5'-UTR, 123 bp in the 3'-UTR, and 969 bp in the open reading frame that encodes a putative protein of 323 amino acids (data not shown; GenBank accession number GU064907). Figure 1A shows the comparison of the deduced amino acid sequence of bovine 20 α -HSD with that of other species. According to a homology search, the nucleotide sequence of bovine 20 α -HSD cDNA showed high homology to other animals (goat 96%, human 84%, rabbit 83%, rat 81%, and mouse 81%). However, the sequence showed very low homology to bovine testicular 20 α -HSD cDNA (49%) reported previously (Warren *et al.* 1993). The bovine testicular 20 α -HSD cDNA encodes a protein of 307 amino acids that is identical to the cDNA of the bovine lens aldose reductase enzyme. Phylogenetic tree analysis of the 20 α -HSD amino acid sequence across various vertebrate species showed that bovine 20 α -HSD clusters with high bootstrap in the lineage of goats and humans, sharing the highest homology with goat 20 α -HSD (Fig. 1B).

Expression of bovine 20 α -HSD mRNA

Using specific primers for 20 α -HSD and amplification by reverse transcriptase-PCR (RT-PCR), we determined the expression levels of 20 α -HSD mRNA in the ovaries obtained from the CL during estrous cycle, the

Figure 1 Comparison of the bovine 20 α -HSD and related sequences. (A) The deduced bovine 20 α -HSD amino acid sequence was aligned with the amino acid sequence of goat, deer, rabbit, human, mouse, and rat 20 α -HSD. Amino acids are presented in the conventional single-letter code and are numbered on the right. The 1F and 3R PCR primers are boxed. Amino acid residues that are completely conserved across the species are indicated by dashed lines. (B) The phylogenetic tree of the bovine 20 α -HSD amino acid sequence was compared with the 20 α -HSD sequences from other vertebrate species. The other 20 α -HSD amino acid sequences were obtained from GenBank, and the phylogenetic tree was constructed using the unrooted analysis with PHYLYP and Tree View.

Figure 2 Expression of the bovine 20 α -HSD gene in the ovary throughout the estrous cycle, the pre-parturition placenta, and in cultured luteum cells. (A) We randomly collected ovaries at different times throughout the estrous cycle. The corpus luteum at the estrous cycle was divided according to CL stages. (B) Placentomes were obtained from cesarean delivery on day 283 of gestation from Korean native bovines. (C) Bovine 20 α -HSD mRNA was detected in cultured corpus luteum cells. The corpus luteum cells of the CH2 stage were cultured until 120 h. (D) The relative expression of the 20 α -HSD gene (mean $\pm$ s.d.) present in three sets of samples evaluated by PCR. Total RNA was extracted and analyzed by RT-PCR. The PCR products were then separated by agarose gel electrophoresis. Representative PCR results are shown. The amplified products of 20 α -HSD and GAPDH were separated by electrophoresis and stained with ethidium bromide. M, DNA size marker; CH, corpus hemorrhagicum; CL, corpus luteum.

placentome on day 283 of pregnancy, and cultured luteal cells; 20 α -HSD was expressed in all ovarian and placentome tissue (Fig. 2A and B). Next, we determined the mRNA expression level in cultured bovine CL cells during the corpus hemorrhagicum (CH) 2 stage. As shown in Fig. 2C, 20 α -HSD mRNA expression was first found at 24 h after culture, and increased 120 h after culture. For northern blot analysis, total RNA was extracted from the CL (CH2, CH3, CL3, CL2, and CL1) during the estrous cycle and from the placentome at pre-parturition. A strong 20 α -HSD mRNA band with a size of $\sim$ 1.2 kb was observed. 20 α -HSD mRNA was not detected in the CL of the CH2, CH3, and CL3 stages, but was strongly detected in the CL2 and CL1 stages (Fig. 3). This pattern was very similar to the RT-PCR result. The 20 α -HSD mRNA expression was also strongly detected in the pre-parturition placenta.

Production of a 20 α -HSD polyclonal antibody

Bovine 20 α -HSD protein was expressed in the *E. coli* system using the pRSET expression plasmid vector, and the protein was purified by diethylaminoethanol (DEAE) column chromatography. Bovine 20 α -HSD protein was detected at the predicted molecular weight of 37 kDa by SDS-PAGE and Coomassie blue staining (Fig. 4A). The recombinant protein was injected three times into two rabbits, and blood was collected after the final injection. One of the rabbits responded to the recombinant protein, and its serum was purified to produce a specific antibody against bovine 20 α -HSD by chromatography.

Expression of recombinant 20 α -HSD in the CHO-K1 cell line

Two expression vectors (pcDNA3+b20 α -HSD and pcDNA4/HisMax+b20 α -HSD) were transiently transfected into CHO-K1 cells, after which the cell lysates were collected and subjected to SDS-PAGE. The specific antibody for 20 α -HSD produced in this study was used to detect the level of the recombinant protein produced by the two expression vectors via western blot analysis. The blots for pcDNA3+b20 α -HSD and pcDNA4/HisMax+b20 α -HSD showed single protein bands with molecular weights of 37 and 41 kDa respectively (Fig. 4B); the size difference was attributed to a 4 kDa tag on the protein expressed by the pcDNA4/HisMax vector.

Western blot analysis in the placenta and CL tissues

As shown in Fig. 5A, a 37 kDa band corresponding to bovine 20 α -HSD protein was detected. A strong signal was detected in the ovaries of the CL3, CL2, and CL1 stages, but no signal was detected in the ovaries of the CH2 and CH3 stages. The 20 α -HSD protein level was the highest in the CL undergoing luteolysis throughout the estrous cycle. Comparison of the level of 20 α -HSD protein with that of mRNA in the ovaries during the estrous cycle showed a similar pattern. The protein expression level was also assessed in the normal placenta (Fig. 5B) and was robustly expressed on the cotyledon side of the placenta before parturition.

Analysis of 20 α -HSD enzymatic activity of the purified protein

The enzymatic activity of bacterially expressed protein is shown in Fig. 6. One unit of enzymatic activity was defined as the amount of enzyme that catalyzed the formation of 1 nmol NADPH/min. Purified 20 α -HSD protein showed enzymatic activity in a dose-dependent manner (0–25 μ g).

Figure 3 Northern blot analysis of bovine 20 α -HSD mRNA expression throughout the estrous cycle in the ovaries and pre-parturition placenta. (A) Northern blot analysis with 10 μ g total RNA/lane. (B) The relative expression of 20 α -HSD is presented. The blots shown are the results of a representative experiment. CH, corpus hemorrhagicum; CL, corpus luteum; PI, placenta. 18S rRNA was used as a loading control.

Figure 4 Expression of bovine 20 α -HSD protein in *E. coli* and CHO cell lines. (A) SDS-PAGE of purified recombinant 20 α -HSD. *E. coli* transfected with pRSET+b20 α -HSD was cultured, and the purified recombinant bovine 20 α -HSD protein was separated by SDS-PAGE. (B) Bovine 20 α -HSD recombinant protein produced in CHO-K1 cells was analyzed by immunoblot. The bands corresponding to the protein produced by pcDNA3+b20 α -HSD and pcDNA4/HisMax+b20 α -HSD vectors were detected. After gel electrophoresis, the proteins were transferred to a nitrocellulose membrane, and the protein was detected with bovine 20 α -HSD antiserum followed by staining with goat anti-rabbit IgG-POD. Lane 1, pcDNA3+b20 α -HSD; lane 2, pcDNA4/HisMax+b20 α -HSD.

Immunolocalization of 20 α -HSD in the ovary during the estrous cycle

To determine the cell types that are responsible for 20 α -HSD protein expression in the ovary, we performed immunohistochemical analysis on luteal cells of the ovaries during the estrous cycle. As shown in Fig. 7, 20 α -HSD was strongly localized in the large luteal cells and was; especially intense in the CL of the ovaries at the terminal stage of the estrous cycle. Notably, Fig. 7 shows that 20 α -HSD was mainly expressed in the large luteal cells. We also determined the localization of 20 α -HSD in cultured bovine and rat luteal cells. The data shown in Fig. 8 indicate that this protein is expressed in both bovine and rat cultured corpus luteal cells. 20 α -HSD was mainly localized around the nucleus in the cultured CL cells.

Discussion

This is the first report describing 20 α -HSD expression in the ovarian and placental tissues of a bovine species. It was expected that the expression and localization studies would reveal a stage-specific expression pattern in bovine ovaries. Although bovine testicular 20 α -HSD was cloned, the sequence showed very low homology to that of other animals. Bovine testicular 20 α -HSD has weak 20 α -HSD activity, and it markedly differs from the ovarian enzyme with respect to its amino acid sequence (Warren *et al.* 1993). Bovine testicular 20 α -HSD encoded a protein of only 307 amino acids, and the nucleotide sequence was identical to the bovine lens aldose reductase enzyme. Based on the expression pattern and activity, these results suggest that gene cloned in this study is bovine 20 α -HSD cDNA.

Phylogenetic analysis revealed that bovine 20 α -HSD was evolutionarily closer to the cloned goat 20 α -HSD sequence but more distantly related to the rat and mouse sequences. Although the amino acid sequence of bovine 20 α -HSD shares about 66–68% identity with other mammals, the specific regions of the AKR family are conserved across various species (Jez *et al.* 1997, Jayasekara *et al.* 2004). Several conserved sequence patterns were found in the bovine 20 α -HSD cloned in this study. The catalytic tetrad such as Asp 50, Tyr 55, Lys 84, and His 117 is a common feature of the AKR family (Penning 1997). Other amino acids such as Gly 22, Gly 45, Asp 112, Pro 119, Gly 164, Asn 167, Pro 186, Gln 190, and Ser 271 are strictly conserved in the primary structure of all the members of the AKR family (Jez *et al.* 1997). Thus, these amino acids may play a role in conferring the appropriate tertiary structure necessary for functional activity.

The mRNA expression analysis shows that the enzyme is strikingly lower in the ovaries of the CH2 and CH3 stages; however, levels were remarkably higher in the CL of the late estrous cycle and placenta before parturition, thus suggesting its important role in the production of ovarian 20 α -HSD during the late estrous cycle and in the placenta during pregnancy. Goat 20 α -HSD was expressed in the placenta and intercaruncular part of the uterus during mid-to-late pregnancy but not in the adrenal gland, liver, or spleen during pregnancy (Jayasekara *et al.* 2004, 2005). Human 20 α -HSD is highly expressed in the liver, mammary gland, and brain, whereas its expression is lower in the prostate, testis, and uterus and is remarkably low in the adrenal gland (Zhang *et al.* 2000). However, in our study, we did not detect 20 α -HSD expression in other tissues, except the placenta, ovary, and cultured luteal cells. The expression of 20 α -HSD in cultured bovine CL cells was consistent with its expression in rat cells; i.e. the amount of 20 α -HSD mRNA increased spontaneously in a time-dependent manner (Hirabayashi *et al.* 2004).

Figure 5 Western blot analysis of the bovine ovary during the estrous cycle and pre-parturition placenta. (A) Corpus luteum tissues throughout the estrous cycle (CH2, CH3, CL3, CL2, and CL1). (B) The placentome was collected on day 283 of pregnancy. Placentas were divided into the caruncle and cotyledon. β -Actin was used as the loading control; Caru, Caruncle; Coty, Cotyledon.

Figure 6 Catalytic activity of bacterially expressed purified 20 α -HSD protein. The enzyme activity was measured by spectrophotometry. Each point represents the mean values of three separate experiments.

Northern blot analysis revealed that bovine 20 α -HSD mRNA was markedly expressed in the placenta at the end of pregnancy. Moreover, these results may provide insight into the role of the 20 α -HSD gene at the above mentioned phases of pregnancy. Our data were closely consistent with the results from previous studies that indicated that 20 α -HSD mRNA was highly expressed at the end of pregnancy and during the late estrous phase (Albarracin *et al.* 1994, Jayasekara *et al.* 2004).

Bovine AKR1B5/PGFS, which mediates 20 α -HSD activity, was highly expressed during the estrous cycle and in endometrial cell cultures at times immediately preceding the expected production of PGF_{2 α} (Madore *et al.* 2003). 20 α -HSD/PGFS (AKR1B5) was widely expressed in uninucleated trophoblast cells of chorionic villi in a more constitutive manner (Schuler *et al.* 2006). AKR1B5 expression peaks around day 12, with progesterone simultaneously reaching its highest systemic concentration. Its expression is different from the bovine 20 α -HSD gene, which is highly expressed during the late estrous cycle in this study. To verify the enzymatic activity of the recombinant 20 α -HSD that was produced and purified in a bacterial system, we analyzed the rate of conversion of NADP to NADPH in the presence of 20 α -OHP. 20 α -HSD activity was recorded at ~ 1.6 nmol/min per μ g protein and showed enzymatic activity similar to other species (Jayasekara *et al.* 2004), thus confirming that the isolated cDNA was indeed bovine 20 α -HSD cDNA. Although AKR1B5 has inactivated progesterone, the gene has weak 20 α -HSD activity and a different number of amino acids (Warren *et al.* 1993). We cautiously suggest that the 20 α -HSD/PGFS (AKR1B5) may not be the genuine 20 α -HSD gene and hold that the gene cloned in this study is the actual bovine 20 α -HSD gene as demonstrated by our results regarding expression and activity.

20 α -HSD protein expression was only detected in the ovaries of the CL3, CL2, and CL1 stages throughout the estrous cycle; it was also robustly expressed in the cotyledon side of the placenta just before parturition. 20 α -HSD expression increased according to the phase of the estrous cycle, and mostly mirrored the mRNA expression pattern. This observation is consistent with

previous reports showing the presence of 20 α -HSD mRNA (Stickler *et al.* 1981, Ishida *et al.* 1999, Nakajima *et al.* 2003, Jayasekara *et al.* 2004) and protein (Shiota *et al.* 1993, Seong *et al.* 2002) in the placenta. However, both rat 20 α -HSD protein and mRNA were undetectable until just before parturition, during which the enzyme was abundantly expressed (Albarracin *et al.* 1994). The bovine placenta was shown to express considerable 20 α -HSD, as in goat (Jayasekara *et al.* 2004) and deer placental tissues (P Naidansuren, CW Park, T Nanjidsuren, JJ Park, SJ Yun, BW Sim, MH Kang & KS Min, unpublished data). Bovine 20 α -HSD protein was intensely localized to large luteal cells at the late estrous cycle. This is the first study to investigate the localization of bovine 20 α -HSD protein in the ovary during the estrous cycle. In rats, immunoreactivity of the 20 α -HSD protein was revealed in decidual cells and trophoblastic giant cells on day 10 and spongiotrophoblasts and visceral yolk sac cells on day 21 of pregnancy (Shiota *et al.* 1993). We also determined that the expression of 20 α -HSD was mainly localized around the nucleus in cultured CL cells. The abrupt expression of 20 α -HSD at the end of pregnancy may be partly due to the expression of PGF_{2 α} , the level of which increases at the end of pregnancy. PGF_{2 α} markedly stimulates the activity of 20 α -HSD, and the molecular mechanism underlying this stimulation has not yet been elucidated (Stocco *et al.* 2000, 2002). Bovine 20 α -HSD mRNA and protein were markedly expressed in the late estrous cycle, which is consistent with the view that functional luteolysis is associated with an increase in 20 α -HSD activity. In addition to ovary, the expression of bovine 20 α -HSD in the placenta

Figure 7 Localization of bovine 20 α -HSD protein expression in the CL throughout the estrous cycle by immunohistochemistry. Representative immunohistochemical analyses using 20 α -HSD antiserum (1:1000) and goat anti-rabbit secondary antibodies (1:500). Preimmune serum (1:1000) was used for primary antiserum as the negative control. Immunohistochemistry was performed by a Vectastain ABC kit. Ovarian sections are shown during the estrous cycle. Preimmune serum was used as the control for the CL stage 7 below the right panel. Black bar = 100 μ m. Red arrows indicate luteal cells.

Figure 8 Bovine 20 α -HSD expression in cultured bovine and rat corpus luteum cells by immunofluorescence. Counter staining was performed with DAPI (blue). Bovine 20 α -HSD expression was detected by Alexa 488 (green). The merged picture shows blue and green colors. (A) Bovine luteal cells. (B) Rat corpus luteal cells. White bars = 100 μ m.

may greatly contribute to the progression of pregnancy by controlling peripheral progesterone concentrations.

In summary, we identified the nucleotide sequence and expression pattern of the 37 kDa protein located specifically in the luteal cells and characterized the protein as 20 α -HSD, a member of the AKR family of enzymes. Our study also demonstrated that 20 α -HSD mRNA and protein are coordinately expressed in the CL throughout the estrous cycle. Thus, the bovine 20 α -HSD gene might control important mechanisms during the estrous cycle. The fact that recombinant 20 α -HSD can be expressed and readily purified using bacterial and mammalian expression systems indicates that these are excellent choices for exploring the detailed mechanism of action of multifunctional enzymes. 20 α -HSD mRNA and protein were highly upregulated in the cotyledon of the placenta at the end of pregnancy. Further studies are needed to determine the functional significance of bovine 20 α -HSD during pregnancy and parturition.

Materials and Methods

Materials

The cloning vector pCR2.1, expression vectors pcDNA3 and pcDNA4/HisMax, GeneRacer Kit, and the Super Script

First-Strand Synthesis System were purchased from Invitrogen Life Technologies. Restriction enzymes and the DNA ligation kit were purchased from Takara (Tokyo, Japan). The One-step SYBR RT-PCR kit was purchased from ToYoBo (Osaka, Japan). PRO-PREP protein extraction solution was purchased from Intron Biotechnology (Seoul, Korea). The digoxigenin (DIG) DNA labeling kit and the Lumi-Light western blot kit were bought from Roche. Horse serum, goat serum, the avidin-biotin-HRP (ABC) detection kit, 3,3'-diaminobenzidine (DAB), hematoxylin and methyl green were purchased from Vector Laboratories (Burlingame, CA, USA). Anti-rabbit immunoglobulins and Alexa 488 secondary antibody were purchased from Dako Cytomation (Glostrup, Denmark). *E. coli* competent cells were from Yeastern Biotech Co. Ltd. (Seoul, Korea). Serum-free CHO-S-SFM II and Lipofectamine 2000 reagents were purchased from Gibco BRL. Fetal bovine serum (FBS) was obtained from Hyclone Laboratories (Logan, UT, USA). The oligonucleotides were synthesized by Genotech (Daejeon, Korea), and all other chemicals were obtained from local suppliers.

Tissues

Placental tissues were obtained from cesarean delivery on day 283 of gestation. The placentas were collected and stored at -80°C until use. CL tissues were classified into five groups according to the stage of estrous cycle that was based on the ovarian morphology as follows: days 4–6 (CH2), 7–12 (CH3), 13–15 (CL3), 16–18 (CL2), and 19–21 (CL1). CH (CH2 and CH3) and CL (CL3, CL2 and CL1) samples were divided into the CL classes as previously reported (Arosh *et al.* 2002). All experiments were conducted according to the Guidelines for the Care and Use of Animals, Hankyong National University.

Preparation of the bovine 20 α -HSD cDNA fragment

The primers for PCR were designed according to the homologous part of the 20 α -HSD cDNA sequence as previously reported (Lacy *et al.* 1993, Mao *et al.* 1994, Ishida *et al.* 1999, Jayasekara *et al.* 2004). The specific primers (sense: 5'-GTG AAG AGA GAA GAC ATA TTC-3' and antisense: 5'-CCA CGT TGT ATC TGG TAG CGA AGG-3') were also synthesized from the nucleotide sequence of the cloned 20 α -HSD gene. Total RNA was extracted using the Trizol reagent (Invitrogen), and cDNA synthesis was performed by the SuperScript First-Strand Synthesis System according to the manufacturer's instructions. Next, PCR was carried out using 2.5 units of *Pfu* polymerase on Quick Thermo-II and consisted of 30 cycles of denaturation (91°C for 1 min), annealing (37°C for 1 min), and extension (72°C for 2 min). The PCR products were analyzed by electrophoresis in Tris-acetate buffer containing EDTA. The PCR fragments (572 bp) were ligated into the pCR2.1 vector, and sequence data were analyzed using computer software (DNASIS).

3'- and 5'-RACE

GeneRacer 3'-primer (5'-GCT GTC AAC GAT ACG CTA CGT AAC G-3') and GeneRacer 3'-nested primer (5'-CGC TAC GTA ACG GCA TGA CAG TG-3') for 3'-RACE were designed

according to the nucleotide sequence of the resulting PCR product. The gene-specific primer GeneRacer 5'-primer (5'-CGA CTG GAG CAC GAG GAC ACT GA-3') and GeneRacer 5'-nested primer (5'-GGA CAC TGA CAT GGA CTG AAG GAG TA-3') for 5'-RACE were designed according to the nucleotide sequence of the resulting PCR product. The 3'- and 5'-RACE were performed by the GeneRacer Kit (Invitrogen) according to the manufacturer's instructions.

RT-PCR and northern blotting analysis

RT-PCR was performed by the AccuPower RT-PCR kit (RT/PCR PreMix). Total RNA (1.0 μ g) extracted from the bovine ovary, placenta, and CL was mixed with the reverse primer (5'-GCC ATT GCC AAA AAG CAC AAG-3'), incubated at 70 °C for 5 min, and then placed on ice. The forward primer (5'-GGA AAG CGG ATA GTC AGG GTG ATC-3') was then added, and the reaction volume (20 μ l) was attained with diethylpyrocarbonate-distilled water. The cDNA synthesis reaction was performed by the following protocol: 42 °C for 60 min and 94 °C for 5 min. PCR was carried out according to the following protocol: 94 °C for 1 min, followed by 30 cycles of 94 °C for 1 min, 56 °C for 1.5 min, and 72 °C for 1 min. This was followed by a final extension at 72 °C for 8 min. RNA electrophoresis was performed on an agarose gel containing 10 $\times$ 3-(4-morpholino) propane sulfonic acid and 37% formaldehyde, and the total RNA concentration from bovine placenta and CL was diluted to 10 μ g/ μ l. After electrophoresis, the RNA was transferred onto a membrane with 20 $\times$ saline-sodium citrate and incubated overnight. The probe was prepared by purifying the sample after PCR amplification. Probe labeling was performed by the DIG DNA labeling kit. The membrane was pre-hybridized for 1 h at 68 °C and hybridized at 68 °C overnight with DIG-labeled bovine 20 α -HSD cDNA with gentle rocking. The bands were visualized the following day using an antibody conjugate and X-ray film for exposure.

Production of polyclonal antibody

The pRSET vector containing bovine 20 α -HSD full-length cDNA was constructed and transformed into *E. coli*. Three colonies were selected to produce the recombinant protein. The protein was purified by DEAE column chromatography. Next, 5 μ g protein was coupled to 5 mg maleimide-activated keyhole limpet hemocyanin according to the manufacturer's instructions. The conjugated protein was emulsified with an equal volume of Freund's complete adjuvant and s.c. injected into rabbits. One month after the initial injection, the rabbits were boosted with $\sim$ 200 μ g protein in an equal volume of incomplete Freund's adjuvant. Booster injections were then repeated at 2-week intervals. Total blood was collected and tested by western blot for recombinant bovine 20 α -HSD prepared from CHO-K1 cells. Only one rabbit injected with the recombinant protein developed antibodies against it. Finally, IgG fractions were prepared from the rabbit immune sera using protein-A chromatography.

Construction of expression transfer vector and transient transfection into CHO cell lines

Bovine 20 α -HSD genes cloned into the pCR2.1 vector were digested with XhoI and XbaI restriction enzymes. The digested fragments were ligated into eukaryotic expression vectors (pcDNA3 and pcDNA4/His Max) that had been digested with XhoI and XbaI. Each vector was completely sequenced to confirm the presence of the Kozak site and to rule out the possibility of any PCR errors. CHO-K1 cell lines were cultured in growth medium (Ham's F12 media containing penicillin (50 U/ml), streptomycin (50 mg/ml), glutamine (2 mM), and 10% FCS) and incubated at 37 °C in 5% CO₂. Cultured CHO-K1 cells were transfected with the expression vectors by the liposome transfection method described previously (Min *et al.* 2004). After 4–6 h of transfection, 250 μ l 20% FBS was added to the wells, and the cells were maintained at 37 °C in a CO₂ incubator for 24 h. On the following day, the transfected cells were washed twice, and then 500 μ l serum-free medium was added and the cells were incubated at 37 °C for 48 h. The culture media was then removed, and the cells were collected into a tube. The cells were centrifuged at 13 000 *g* for 10 min, and the cell debris was recovered.

Measurement of 20 α -HSD enzymatic activity

20 α -HSD enzymatic activity of the purified protein was measured by spectrophotometry as previously reported (Jaya-sekara *et al.* 2004). Briefly, enzymatic activity was determined by the rate of conversion of NADP to NADPH in the presence of 20 α -OHP. The enzymatic reaction was initiated by adding various amounts of purified 20 α -HSD protein, and the absorbance was measured at 340 nm. The enzymatic activity was defined as the amount of enzyme that catalyzed the formation of 1 nmol NADPH/min.

Bovine and rat CL cell culture

Bovine CL cells were cultured from the ovary at the CH2 stage. First, the CL tissues were washed twice with 1 $\times$ PBS and cut into 0.5 cm sections in DMEM. The tissues were then cultured with 0.2% collagenase at 37 °C in a shaking incubator for 2 h. The culture medium was filtered through a cell strainer and centrifuged at 1000 *g* for 5 min, after which the supernatant was collected. Finally, cells were counted using a cytometer, and 2 $\times$ 10⁶ cells were seeded onto a cell culture plate. Twenty six-day-old immature female Wistar rats housed in our laboratory were s.c. injected with 50 U equine chorionic gonadotropin, and after 42 h they were i.p. injected with 10 U human chorionic gonadotropin (hCG). After 6 h, the rats were killed by decapitation, and the ovaries were isolated and collected in DMEM medium. The rat CL tissues were cultured in the same manner as the bovine CL cells.

Western blot analysis

Total proteins were extracted using the PRO-PREP protein extraction solution. Approximately 10–20 mg ovarian and placental tissues were used. The tissues were minced and transferred to appropriate tubes. The samples were then

homogenized in 600 µl PRO-PREP solution, and cell lysis was induced by incubating the cells for 30 min on ice. Finally, the samples were centrifuged at 105 000 *g* at 4 °C for 5 min, and the supernatants were transferred to fresh 1.5 ml tubes. The protein concentration was measured by the Bradford method (Bradford 1976). Samples were separated by SDS-PAGE and transferred to a PVDF membrane using a semidry electroblotter apparatus. After blotting, the membrane was blocked with a 1% blocking reagent for 1 h and incubated with a 1:1500 dilution of a polyclonal 20 α -HSD antibody for 1 h. The membrane was washed to remove unbound antibody and was then incubated with a 1:2000 dilution of a secondary antibody linked to anti-rabbit IgG-peroxidase for 30 min. Next, the membrane was incubated for 5 min with 2 ml Lumi-Light substrate solution, following which the solution was discarded. The membrane was placed on Saran Wrap, covered with another layer of Saran Wrap, and exposed to X-ray films for 1–10 min.

Immunohistochemistry

Immunohistochemical staining of CH2, CH3, CL3, CL2, and CL1 samples was performed by the Vectastain ABC kit (Vector Laboratories). The samples were fixed in 10% neutral buffered formalin at room temperature for 24 h and washed with PBS. Next, the fixed samples were rehydrated in graded ethanol (3 min each in 100% 2 $\times$; 95% 1 $\times$; 70% 1 $\times$; 50% 1 $\times$) and embedded in paraffin. Paraffin-embedded tissues were sectioned into 8 µm slices, which were then mounted onto poly-L-lysine-coated slides. The slides were boiled in 10 mM sodium citrate for 10 min and chilled on ice for 20 min. They were then washed in 3% hydrogen peroxide for 10 min and blocked for 1 h at room temperature. The slides were incubated with the primary antibody followed by an anti-rabbit secondary antibody. Finally, the slides were immunostained using the ABC detection kit and stained with DAB. Bovine and rat CL cells were cultured at up to 80–95% confluency on poly-D-lysine-coated chamber slides for 24 h. The attached cells were washed with 1 $\times$ PBS, fixed in 4% paraformaldehyde at room temperature for 20 min, and dried at 37 °C on a heat block for 5 min. The slides were washed in 0.2% Triton X-100. They were incubated with the primary antibody (bovine 20 α -HSD polyclonal antibody) and then an Alexa 488-conjugated anti-rabbit secondary antibody. Finally, the slides were counter stained with 4,6-diamidino-2-phenylindole and mounted. The slides were observed using a Nikon Eclipse TE-2000-E confocal microscope.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research reported.

Funding

This work was funded by a grant (code #20080401034074) from the BioGreen 21 Program, Rural Development Administration, South Korea.

Acknowledgements

The authors thank Dr Y C Chang (Catholic University) and Dr H W Seong (Institute of Animal Science) for their helpful discussions and to Mrs Y S Kang for her technical assistance.
