Abstract

The follicular hierarchy in broiler breeder chicken ovary is often deranged due to excessive ovarian follicular recruitment, resulting in a condition that resembles polycystic ovary syndrome (PCOS) in women. Metformin is widely prescribed to correct PCOS and has been shown to affect granulosa cell functions in humans and rodent models. The objectives of this study are to determine the effects of metformin on signal transduction pathways, gene expression related to steroidogenesis, and progesterone secretion from granulosa cells isolated from the most recently recruited preovulatory and prehierarchical follicles of broiler breeder chickens. Granulosa cells were treated with 0, 1, 10, or 20 mM of metformin in the presence of FSH. The abundance of pAMPK, pACC, pERK, and pAkt was determined by Western blotting. The expression of genes related to progesterone biosynthesis was quantified by qPCR. Progesterone concentrations in culture media were quantified by ELISA. Metformin treatment did not have an effect on the abundance of pAMPK and pACC in prehierarchical follicles but significantly decreased the abundance of pERK and pAkt in a dose-dependent manner in preovulatory and prehierarchical follicles. The expression of genes related to steroidogenesis such as *FSHR*, *STAR*, *CYP11A1*, *HSD3B*, and progesterone secretion was significantly decreased in response to metformin treatment in a dose-dependent manner. Our data suggest that metformin treatment attenuates progesterone secretion via AMPK-independent pathways in granulosa cells of prehierarchical and preovulatory follicles of broiler breeder hens. Further studies are required to determine if metformin administration could ameliorate ovarian dysfunction in obese broiler breeder hens.

Reproduction (2020) **160** 659–672

Introduction

In order for the leghorn chicken to produce a sequence (or clutch) of eggs, they must maintain a small cohort of viable, undifferentiated (prehierarchical) follicles. A single prehierarchical follicle is recruited daily from this cohort into the preovulatory pool of follicles and undergoes rapid growth and differentiation prior to ovulation (Johnson 2015). In the leghorn hen, a prolific egg producer ovulating approximately every 25 h for almost a year, there are few problems with ovarian follicular recruitment, largely due to decades of genetic selection favoring egg production. In contrast, broiler breeder hens, the parent stock of commercial broiler chickens, are genetically selected for faster and efficient body growth in their progenies. As a consequence, broiler breeders have poor reproductive efficiency potentially due to rapid somatic growth and increased adiposity, thus resulting in severe ovarian dysfunction. Full-fed broiler breeder hens display heavier ovaries, excessive follicular recruitment, double ovulation, or increased incidence of ovarian regression (Yu *et al.* 1992a). The hyper-recruitment of prehierarchical follicles and a deranged preovulatory follicular hierarchy often leads to

decreased egg production, lower percentages of fertility and hatchability of eggs, and decreased viability of embryos (Yu *et al.* 1992a).

Although the exact mechanisms underlying ovarian dysfunction in broiler breeder hens still remain elusive, previous studies have shown this could possibly be related to obesity-induced metabolic dysfunction and lipotoxicity (Cassy *et al.* 2004, Chen *et al.* 2006, Walzem & Chen 2014). Previous studies in which broiler breeder hens were allowed to consume feed ad libitum reported irregular metabolic and steroid hormonal profiles, including increased production of androstenedione by small white follicles, increased plasma levels of androstenedione, decreased levels of estradiol-17 β and increased levels of plasma insulin and glucose (Yu *et al.* 1992b, Chen *et al.* 2006, Pan *et al.* 2012). These studies also reported conditions related to metabolic disorder, such as increased plasma concentrations of triglycerides, non-esterified fatty acids, very-low density lipoproteins, ceramide levels, and excessive circulating saturated fatty acids (Chen *et al.* 2006, Pan *et al.* 2012). Interestingly, many of the abnormal ovarian and biochemical changes in broiler breeder hens appear to be similar to a condition in women known as polycystic ovary syndrome (PCOS),

including the biochemical hallmark of increased plasma levels of androgens (Pasquali & Casimirri 1993). PCOS is most commonly associated with obesity, metabolic syndrome, irregular steroid hormone production, irregular ovulation, and poor fertility, all of which have been previously observed in broiler breeder hens (Pasquali *et al.* 2003, Walzem & Chen 2014).

Metformin, a biguanide compound, is commonly prescribed for the treatment of polycystic ovary syndrome and is aimed to correct insulin resistance that is often encountered in women with PCOS. Treatment with metformin has been associated with increased ovulation, fertilization and pregnancy rates (Velazquez *et al.* 1997, Vandermolen *et al.* 2001), normalization of the endocrine profile, as well as a return to normal menstrual cyclicity (Morin-Papunen *et al.* 1998, van Santbrink *et al.* 2005, Tang *et al.* 2006) in women with PCOS. These effects have generally been attributed to the systemic antihyperglycemic and insulin-sensitizing effects of metformin (Prager *et al.* 1986, Perriello *et al.* 1994), but studies have shown that metformin is able to exert direct effects on the ovary and directly inhibit ovarian steroidogenesis (Ehrmann *et al.* 1997, Vrbikova *et al.* 2001, Bertoldo *et al.* 2014). Previous studies have shown that treatment with metformin decreased the abundance of proteins related to steroidogenesis and decreased secretion of progesterone and estradiol from human, bovine and rat granulosa cells (Mansfield *et al.* 2003, Tosca *et al.* 2006b, 2007, Rice *et al.* 2009). However, the effects of metformin on chicken ovarian follicular cells have never been investigated. A better understanding of the cellular effects of metformin at the ovarian level could elucidate pathways that could be targeted for increasing egg production in broiler breeder hens.

In the present study, we hypothesized that treatment of broiler breeder hen granulosa cells with metformin affects FSH-induced signaling networks involving follicular cell proliferation, differentiation, and steroidogenesis. The main objectives of the present study are (i) to determine the molecular mechanisms by which metformin affects FSH-induced signal transduction events in granulosa cells isolated from the most recently recruited preovulatory follicle and prehierarchical follicles, (ii) to determine if metformin affects the expression of genes related to steroidogenesis in granulosa cells, and (iii) to determine the extent to which metformin affects progesterone secretion from granulosa cells.

Materials and methods

Animals and reagents

All animal procedures described herein were approved by Pennsylvania State University's Institutional Animal Care and Use Committee. A commercial strain of broiler breeder hens (Cobb 500) was maintained from day-old chicks at the Poultry Education and Research Center at The Pennsylvania State University (University Park, PA). The chickens were reared

according to the Cobb 500 Breeder Management Guide and photostimulated beginning at 21 weeks of age. The light was increased accordingly as they came into lay and were provided with a 16 h light:8 h darkness cycle photoperiod for the duration of the study. The broiler breeder hens were feed-restricted according to the Cobb Breeder Management Guide and provided with water *ad libitum*. To ensure ovulation had yet to occur at the time of killing, hens were palpated via the cloaca for the presence of a hard-shelled egg in the shell gland.

Tissue collection and granulosa cell cultures

Broiler breeder hens (35–45 weeks old) were killed by cervical dislocation to collect the ovary. Ovarian follicles were grouped by stage of maturation into prehierarchical follicles (3–5 and 6–8 mm) and preovulatory follicles (9–12 mm and F5/6). The granulosa cell layer from each follicle was collected as described previously (Krzysik-Walker *et al.* 2007, Maddineni *et al.* 2008) and was pooled from four hens to form one biological replicate ($n=4$). Following three washes in DMEM with high glucose (Sigma Aldrich), granulosa cells were dispersed by gentle repeated pipetting by glass Pasteur pipet as previously described (Tilly & Johnson 1987, Krzysik-Walker *et al.* 2007). Cell viability was determined by trypan blue exclusion test.

Effect of metformin on granulosa cell gene expression and signal transduction

Approximately 140,000–240,000 granulosa cells were placed into each 12 × 75 mm polypropylene tube (VWR, Radnor, PA) containing 1 mL of DMEM supplemented with 2.5% fetal bovine serum (FBS), 1% antibiotic–antimycotic solution (Gibco), 1× non-essential amino acids (Corning), recombinant human FSH (rhFSH; 0 or 10 ng/mL; National Hormone Program, Torrance, AC), and metformin (0, 1, 10, or 20 mM; Sigma Aldrich). Metformin treatment doses were chosen based on some of the previous studies that investigated the effects of metformin *in vitro* (Mansfield *et al.* 2003, Tosca *et al.* 2006, 2007, Kim *et al.* 2018b, Wu *et al.* 2019); however, such concentrations are several-fold higher than the peak plasma concentration of therapeutic doses of metformin in human subjects. The granulosa cell treatments were incubated in a shaking water bath at 41°C (chicken body temperature) under ambient air conditions. The cultures were incubated for 1 or 3 h to determine phospho-AMPK (pAMPK), phospho-ERK (pERK), phospho-ACC (pACC), and phospho-Akt (pAkt) abundance, or to quantify the abundance of *FSHR*, *STAR*, *CYP11A*, and *HSD3B* mRNA, respectively. We chose a 1 h incubation time to determine the effects of metformin on the abundance of phospho-proteins based on pilot studies (Supplementary Fig. 1, see section on [supplementary materials](#) given at the end of this article). Although phospho-protein abundance could be altered by metformin treatment in as little as 15 min, several studies have utilized a much wider range of treatment durations ranging from 1 h to 7 days (Tosca *et al.* 2006, 2007, 2010, Cen *et al.* 2018, Kim *et al.* 2018b, Zhou *et al.* 2019). At the end of the 1 or 3 h treatments, granulosa cells were recovered by centrifugation at 400 g, snap-frozen in liquid nitrogen, and stored at –80°C.

Quantitative real-time PCR analyses

Total RNA from granulosa cells treated with metformin for 3 h was extracted using the RNeasy kit (Qiagen). The quality and quantity of RNA were evaluated using a spectrophotometer (Nanodrop, Wilmington, DE). Following on-column DNase-I (Qiagen) treatment, first-strand cDNA was synthesized by reverse transcribing 1 µg of total RNA using random hexamers (Promega), 1 mM dNTP mixture (Promega), 2U M-MLV reverse transcriptase (New England BioLabs, Beverly, MA) and 1 µL RNase inhibitor (Invitrogen) in 20 µL of total volume. A real-time quantitative PCR (qPCR) was performed using cDNA prepared above (four broiler breeder hens/replicate; $n=3$) for determination of *FSHR*, *STAR*, *CYP11A1*, *HSD3B1* and *RPL19* mRNA abundance as described previously (Maddineni *et al.* 2005, Ramachandran *et al.* 2007). Each reaction was done in duplicates using 100 ng cDNA, 1X PerfeCTa SYBR Green FastMix, Low ROX (Quantabio, Beverly, MA), and 300 nM forward and reverse primers (Table 1). Average critical log-linear threshold (C_T) values for *FSHR*, *STAR*, *CYP11A1*, and *HSD3B1* were expressed as a proportion of *RPL19* mRNA C_T values following $2^{-\Delta\Delta C_T}$ method (Livak & Schmittgen 2001) and analyzed. Each qPCR experiment was repeated at least 3 times to serve as internal replications.

Western blot analyses

Granulosa cells (pooled from four broiler breeder hens/replicate; $n=3$) treated with metformin for 1 h as described above were homogenized in 1× RIPA lysis buffer (pH 7.4 ± 0.1) (Santa Cruz Biotechnology) supplemented with protease inhibitor cocktail, PMSF, sodium orthovanadate and phosphatase inhibitor cocktails A and B (Santa Cruz Biotechnology). After brief centrifugation, the supernatant was saved and protein concentration was determined by colorimetric detection with a bicinchoninic acid (BCA) assay (Thermo Fisher Scientific) according to the manufacturer's protocol. Western blotting analyses were conducted under reducing conditions, as described previously (Hendricks III *et al.* 2009) to quantify pAMPK, pERK, pACC, and pAkt abundance. The type of polyacrylamide gel, the amount of cellular proteins used in

each blot, and the primary antibodies used are provided in Table 2. Following electrophoresis, proteins were transferred to a PVDF or nitrocellulose membrane and blocked for 1 h at room temperature with 5% BSA in TBS supplemented with 0.1% Tween 20 (pH 7.4; TBST). The blots were incubated with the primary antibodies at 4°C overnight. Following a brief wash, membranes were incubated for 1 h at room temperature with goat anti-rabbit (Thermo Fisher Scientific, Cat# 31460; 1:5000) or goat anti-mouse (Thermo Fisher Scientific, Cat# 31430; 1:5000) poly-horseradish peroxidase (HRP) conjugated secondary antibody diluted in blocking solution, respectively. Following washes in TBST, blots were incubated with enhanced chemiluminescent (ECL) Western blotting substrate (Thermo Fisher Scientific) according to the manufacturer's protocol and imaged using ChemiDoc XRS+ Imaging System (Bio-Rad). Bands were scanned into digital images and analyzed by densitometry using Image Lab Software v. 6.0 (Bio-Rad). Following quantification of pAMPK, pERK, pACC, and pAkt signal intensity, the blots were stripped to quantify the abundance of AMPK, ERK, ACC, or Akt (Table 2). For both the phosphorylated and non-phosphorylated target proteins, target band density was normalized to the appropriate loading control prior to analysis, either β-actin or α-tubulin, respectively. β-Actin and α-tubulin, the two cytoskeletal proteins, were selected for normalization as they are least likely to be affected by metformin treatment. The choice of β-actin or α-tubulin for normalization while quantifying a particular target protein was based on the mass so it would not interfere with the bands of the protein of interest. The abundance of pAMPK, pERK, pACC, and pAkt were expressed as a proportion of AMPK, ERK, ACC, or Akt abundance and compared among treatments. Each Western blotting experiment was repeated at least three times to serve as internal replication.

Effect of metformin on granulosa progesterone secretion

Granulosa cells from prehierarchical follicles (6–8 mm) to preovulatory follicles (F5/6 and 9–12 mm) were dispersed by gentle repeated pipetting by glass Pasteur pipet into a single

cell suspension using 0.3% type II collagenase (Worthington Biochemical Corporation, Lakeford, NJ) supplemented with 2% DNase (Promega). Approximately 0.7–1 million cells/well were seeded in gelatinized 12-well polystyrene culture wells (Corning) containing 1 mL of M199 with Earle's salts (Sigma Aldrich) supplemented with 0.2% α -D-glucose (Sigma), 1 $\times$ insulin-transferrin-selenium solution (Corning), 1% antibiotic–antimycotic solution (Gibco) and 1 $\times$ non-essential amino acids (Corning) at 37°C in an atmosphere of 95% air and 5% CO₂. These cells were allowed to attach and grow for 24 h and then cultured for an additional 24, 48, or 72 h. In the absence or presence of rhFSH (100 ng/mL) and metformin (0, 1, 10, or 20 mM). The granulosa cells were cultured at 37°C to sustain the bioactivity of the human origin-rhFSH utilized in the assay. In previous studies conducted in our laboratory, there was no difference in responses from chicken granulosa cells or ovarian surface epithelial cells when cultured at 37°C or 41°C. Cell culture media was subsequently collected and stored at –20°C for future progesterone quantification, and attached granulosa cells were collected in RIPA lysis buffer for protein extraction and quantification as described above.

Progesterone enzyme-linked immunosorbent assay

Granulosa cells ($n=4$ replicates of four broiler breeder hens each) were cultured as described above, and cell culture media collected. Progesterone concentrations in the cell culture media in response to metformin treatment were quantified by a competitive ELISA as previously described for cell culture medium samples (Petroff *et al.* 1997, Hughes *et al.* 2019). Microplates (Corning Costar) were coated with 100 μ L of goat anti-mouse IgG secondary antibody (2 μ g/mL; EMD Millipore) and incubated overnight at 4°C. Unbound antibody was removed from the plate by washing in wash buffer (5 $\times$ MOPS stock and 10% Tween 20; pH 7.2; WB). In total, 100 μ L of monoclonal mouse anti-progesterone primary antibody (57.8 ng/mL; East Coast Bio, North Berwick, ME) was added to each well except the wells designated to test non-specific binding and the plate was sealed and incubated on a shaker for 1.5 h. The plate was washed with WB to remove excess primary antibody. In total, 100 μ L of cell culture media collected from granulosa cell cultures treated with

metformin, progesterone standards to generate a standard curve, or the assay buffer to determine non-specific binding was then added in duplicate wells. Progesterone (Cayman Chemical, Ann Arbor, MI) concentrations for the standard curve ranged from 0.078 to 10 ng/mL, with a two-fold difference between each dilution. The concentration for the lower end of the range was chosen to allow quantification of the least amount of progesterone in media typically expected out of prehierarchical follicular granulosa cells. Cell culture media samples were diluted, if necessary, to fit within the progesterone detection limits of the assay. Cell culture media samples and antibodies were diluted in assay buffer (0.04 M 3-(N-morpholino) propanesulfonic acid, 0.12 M NaCl, 0.01 M EDTA, 0.05% Tween 20, 0.005% chlorhexidine digluconate, and 0.1% gelatin; pH 7.2). The plates were incubated on a plate shaker for 1.5 h followed by washes in WB and then 125 μ L of substrate solution (0.05 M sodium acetate, 0.5 M hydrogen peroxide, and 3,3',5,5'-tetramethyl benzidine (20 mg/mL in dimethyl sulfoxide; TMB) was added to each well. Plates were sealed and incubated at 37°C for 15 min, followed by the addition of 50 μ L of stop solution (0.5 M H₂SO₄). Plates were read in a Victor³ 1420 Multilabel Counter (PerkinElmer, Waltham, MA, USA), and optical density was assessed at 450 nm. All samples were run in duplicates, and each assay was repeated at least 4 times to serve as an internal replication. The intra-assay coefficients of variation for the samples were less than 15%.

Statistical analyses

All data were subjected to ANOVA using the general linear model (GLM) procedure of the Statistical Analysis System (SAS Institute Inc.; Cary, NC) or GraphPad Prism version 8.0.0. Differences among individual means were determined by using a Tukey's HSD test. A probability level of $P \leq 0.05$ is considered statistically significant. Data on the effect of metformin on granulosa cell *STAR*, *FSHR*, *CYP11A1*, and *HSD3B1* mRNA abundance were expressed as fold differences normalized to ribosomal protein gene, *RPL19*. Data on the effect of metformin on granulosa cell pAMPK, pERK, pACC, and pAkt abundance is expressed as a proportion of AMPK, ERK, ACC or Akt abundance, respectively, and compared among

Figure 1 (A–C) Western blot analysis on the effect of metformin on pAMPK and AMPK abundance in granulosa cells. Granulosa cells from prehierarchical follicles (3–5 and 6–8 mm) to preovulatory follicles (9–12 mm) were dispersed into single-cell suspension and treated with 0, 1, 10, or 20 mM metformin for 60 min in the presence or absence of rhFSH (10 ng/mL) at 41°C. Cell lysates were prepared following treatment, and a Western blot analysis was performed under reducing conditions to quantify the abundance of pAMPK, AMPK, and β -actin. Control received no rhFSH and no metformin. β -Actin is used as a protein loading control. ^{A,B} $P < 0.05$ by ANOVA; $n=3$ replicates of four broiler breeder hens each. *Inset*: Photograph of prehierarchical follicles and the most-recently recruited preovulatory follicle to denote the source of granulosa cell (open box).

the treatments. Progesterone concentrations in the cell culture media were normalized to total cellular protein concentrations in each well and analyzed using ANOVA as described above, which also included ELISA plate as a covariate in the model. All data are represented as mean $\pm$ S.E.M.

Results

Effect of metformin on granulosa cell pAMPK and pACC abundance

Metformin treatment had no effect on the abundance of pAMPK in granulosa cells isolated from 3–5 to 6–8 mm prehierarchical follicles (Fig. 1A and B). In contrast, metformin treatment at 1 mM level significantly increased the abundance of pAMPK in granulosa cells isolated from the most recently recruited preovulatory (9–12 mm) follicle while phosphorylation of AMPK in response to metformin treatments at 10 and 20 mM did not differ from the controls (Fig. 1C). The abundance of pACC in granulosa cells isolated from 3–5 to 6–8 prehierarchical follicles and the most recently recruited 9–12 mm preovulatory follicle did not differ in response to metformin treatment when compared to vehicle treatment (Fig. 2A, B and C). However, the abundance of pACC was significantly greater in response to 1 mM metformin treatment when

compared with 20 mM metformin treatment in 9–12 mm follicular granulosa cells.

Effect of metformin on granulosa cell pERK and pAKT abundance

Metformin treatment of granulosa cells isolated from prehierarchical follicles (3–5 and 6–8 mm) to the most-recently recruited preovulatory follicle (9–12 mm) significantly decreased the abundance of pERK and pAkt in a dose-dependent manner, with 10 and 20 mM having the most significant effect (Figs 3 and 4).

Effect of metformin on granulosa cell gene expression

Treatment of granulosa cells isolated from prehierarchical follicles (3–5 and 6–8 mm) to the most-recently recruited preovulatory follicle (9–12 mm) with 1, 10, or 20 mM metformin, significantly decreased the abundance of *FSHR* mRNA (Fig. 5A, B and C). We observed a lesser abundance of *STAR* mRNA in granulosa cells isolated from 6–8 mm to 9–12 mm follicles when treated with metformin at 10 or 20 mM compared to 0 or 1 mM metformin treatment (Fig. 6B and C). However, metformin treatment at 0, 1, 10, or 20 mM levels resulted in a significantly lesser abundance of *STAR* mRNA in 3–5

Figure 2 (A–C) Western blot analysis on the effect of metformin on pACC and ACC abundance in granulosa cells. Granulosa cells from prehierarchal follicles (3–5 and 6–8 mm) to preovulatory follicles (9–12 mm) were dispersed into single-cell suspension and treated with 0, 1, 10, or 20 mM metformin for 60 min in the presence or absence of rhFSH (10 ng/mL) at 41°C. Cell lysates were prepared following treatment, and a Western blot analysis was performed under reducing conditions to quantify the abundance of pACC, ACC, and α-tubulin. Control received no rhFSH and no metformin. α-tubulin is used as a protein loading control. ^{A,B,P} $P < 0.05$ by ANOVA; $n = 3$ replicates of four broiler breeder hens each. mm follicular granulosa cells when compared to the cells that received no metformin and were only stimulated with rhFSH (Fig. 6A). In the same cell population, the abundance of *CYP11A1* mRNA was lesser in response to 20 mM metformin treatment compared to 0 mM level (Fig. 7A). In 6–8 mm follicular granulosa cells, a dose-dependent decrease in *CYP11A1* abundance was observed when treated with metformin at 0, 1, 10, or 20 mM (Fig. 7B). In 9–12 mm follicular granulosa cells, metformin treatment at 1, 10, or 20 mM levels resulted in a lesser abundance of *CYP11A1* mRNA compared to the cells that received no metformin treatment and were only stimulated with rhFSH (Fig. 7C). While metformin treatment had no effect on the abundance of *HSD3B1* mRNA in 3–5 mm follicular granulosa cells, a dose of 10, or 20 mM metformin treatment resulted in a lesser abundance of *HSD3B1* mRNA in 6–8 mm granulosa cells compared to 0 and 1 mM metformin treatment (Fig. 8A and B). A dose-dependent decrease in the abundance of *HSD3B1* mRNA in 9–12 mm follicular granulosa cells was observed in response to 0, 1, 10, or 20 mM metformin treatment (Fig. 8C).

Effect of metformin on progesterone secretion

Treatment of granulosa cells isolated from 6 to 8 mm prehierarchal follicle with 10 or 20 mM metformin

resulted in a decrease in progesterone concentrations back to the levels observed with the control (Fig. 9A, B and C) at 72 h of treatment, but not at 24 and 48 h. A dose-dependent decrease in progesterone concentration was observed when granulosa cells isolated from the most recently recruited preovulatory follicle (9–12 mm) were treated with metformin for 24, 48, or 72 h with 20 mM of metformin having the most-significant effect (Fig. 9D, E and F). Similar to 9–12 mm follicular granulosa cells, treatment of the smallest preovulatory follicle (F5) granulosa cells with metformin decreased progesterone concentrations in a dose-dependent manner at 24, 48 and 72 h of culture with 10 and 20 mM of metformin having the most-significant effect (Fig. 9G, H and I).

Discussion

We report for the first time that metformin decreases progesterone secretion from granulosa cells isolated from prehierarchal and preovulatory follicles of the chicken ovary. Such attenuation of steroidogenesis in response to metformin was associated with a diminished expression of genes related to steroidogenesis and decreased phosphorylation of ERK1/2 and Akt. Our results suggest that metformin in granulosa did not affect the phosphorylation of AMPK in granulosa cells isolated from prehierarchal follicles. However, metformin

Figure 3 (A–C) Western blot analysis on the effect of metformin on pERK1/2 and ERK abundance in granulosa cells. Granulosa cells from prehierarchal follicles (3–5 and 6–8 mm) to preovulatory follicles (9–12 mm) were dispersed into single-cell suspension and treated with 0, 1, 10, or 20 mM metformin for 60 min in the presence or absence of rhFSH (10 ng/mL) at 41°C. Cell lysates were prepared following treatment, and a Western blot analysis was performed under reducing conditions to quantify the abundance of pERK1/2, ERK1/2, and β -actin. Control received no rhFSH and no metformin treatments. β -Actin is used as a protein loading control. $^{A,B,C,P} < 0.001$ by ANOVA; $n = 4$ replicates of four broiler breeder hens each. *Inset*: Photograph of prehierarchal follicles and the most-recently recruited preovulatory follicle to denote the source of granulosa cell (*open box*).

appears to have a biphasic effect on activation of AMPK in granulosa cells of the most-recently recruited 9–12 mm preovulatory follicle, as 1 mM metformin treatment increased pAMPK abundance, an effect that was reversed by higher levels of metformin. The expression of AMPK and its ability to respond to AICAR by increased phosphorylation in granulosa and theca cells of preovulatory follicles (F1–F4) of leghorn chickens has been previously documented (Tosca *et al.* 2006). While no data exists on the effect of metformin on chicken granulosa cells, several studies indicate that metformin treatment increases phosphorylation of AMPK of rat (Tosca *et al.* 2006), bovine (Tosca *et al.* 2007), and human (Kai *et al.* 2015) granulosa cells. A lack of effect on AMPK phosphorylation in response to metformin treatment in the present study potentially reflects species variation and suggest that metformin is least likely to act via AMPK-dependent pathway in undifferentiated granulosa cells. Metformin has been found to act via AMPK-independent pathways such as inhibition of mitochondrial respiration (Owen *et al.* 2000), decreased phosphorylation of ERK1/2 (Tosca *et al.* 2007), downregulation of mTORC (Kalender *et al.* 2010) and a decrease in the production of cAMP (Miller *et al.* 2013). In addition, metformin decreases hepatic gluconeogenesis by inhibiting several enzymes involved in gluconeogenesis in an AMPK-independent manner (Foretz *et al.* 2010). Taken together,

metformin treatment at all dosages is likely to be acting primarily through an AMPK-independent pathway in undifferentiated granulosa cells of prehierarchal follicles but may act by either AMPK-independent or AMPK-dependent pathways depending on the dose in actively differentiating granulosa cells.

We investigated the effect of metformin on the abundance of ACC due to the critical role of pACC in decreasing fatty acid synthesis by inhibiting the conversion of acetyl-CoA to malonyl-CoA (Fullerton *et al.* 2013). Our results suggest that metformin had no effect on phosphorylation of ACC in granulosa cells isolated from prehierarchal follicles or the most recently recruited preovulatory follicle. Given that metformin did not affect AMPK phosphorylation in our study, it is not surprising to expect a lack of effect of metformin on phosphorylation of ACC, which is one of the pAMPK downstream targets. While this data may confirm the dependency of ACC for its activation on activation of AMPK, further studies are essential to clarify the role of metformin on granulosa cell fatty acid metabolism as it is related to energy homeostasis and steroidogenesis.

Our data suggest that metformin decreases the phosphorylation of ERK2, in a dose-dependent manner, in granulosa cells isolated from both prehierarchal follicles and the most recently recruited preovulatory

Figure 4 (A–C) Western blot analysis on the effect of metformin on pAKT and AKT abundance in granulosa cells. Granulosa cells from prehierarchal follicles (3–5 and 6–8 mm) to preovulatory follicles (9–12 mm) were dispersed into single-cell suspension and treated with 0, 1, 10, or 20 mM metformin for 60 min in the presence or absence of rhFSH (10 ng/mL) at 41°C. Cell lysates were prepared following treatment, and a Western blot analysis was performed under reducing conditions to quantify the abundance of pERK1/2, ERK1/2 and β -actin. Control received no rhFSH and no metformin treatments. β -Actin is used as a protein loading control. ^{A,B,C} $P < 0.001$ by ANOVA; $n = 4$ replicates of four broiler breeder hens each. *Inset*: Photograph of prehierarchal follicles and the most-recently recruited preovulatory follicle to denote the source of granulosa cell (open box).

Figure 5 (A–C) Effect of metformin on *FSHR* mRNA abundance in granulosa cells. Granulosa cells from prehierarchal follicles (3–5 and 6–8 mm) to preovulatory follicles (9–12 mm) were dispersed into single-cell suspension and treated with 0, 1, 10, or 20 mM metformin for 180 min in the presence or absence of rhFSH (10 ng/mL) at 41°C. Control received no rhFSH and no metformin treatments. Total RNA extracted from granulosa cell to reverse transcribed. Approximately 100 ng of cDNA was used in quantitative PCR to quantify *FSHR* mRNA or *RPL19* mRNA in separate reactions. Each reaction was run in duplicates, and the critical threshold (C_T) values were averaged, subtracted from that of *RPL19* mRNA, and converted from log-linear to linear terms. Data were standardized to *RPL19* mRNA and expressed as fold-difference vs control. ^{A,B,C} $P < 0.001$; $n = 4$ replicates of four broiler breeder hens each. *Inset*: Photograph of prehierarchal follicles and the most-recently recruited preovulatory follicle to denote the source of granulosa cell (open box).

Figure 6 (A–C) Effect of metformin on *STAR* mRNA abundance in granulosa cells. Granulosa cells from prehierarchal follicles (3–5 and 6–8 mm) to preovulatory follicles (9–12 mm) were dispersed into single-cell suspension and treated with 0, 1, 10, or 20 mM metformin for 180 min in the presence or absence of rhFSH (10 ng/mL) at 41°C. Control received no rhFSH and no metformin treatments. Total RNA was extracted and subjected to quantitative real-time PCR as described in the legend to Fig. 5. Data were standardized to *RPL19* mRNA and expressed as fold-difference vs control. ^{A,B,C}*P* < 0.001; *n* = 4 replicates of four broiler breeder hens each. *Inset*: Photograph of prehierarchal follicles and the most-recently recruited preovulatory follicle to denote the source of granulosa cell (*open box*).

follicle. These results are consistent with previous reports of metformin inhibiting the phosphorylation of ERK1/2 in bovine and rat granulosa cells (Tosca *et al.* 2006, 2007). Activation of mitogen-activated protein kinases (MAPK) results in phosphorylation of several cytoplasmic substrates affecting cellular proliferation and steroidogenesis in human, bovine, and rat granulosa cells (Tajima *et al.* 2003, 2005, Tosca *et al.* 2005, 2006, Zhou *et al.* 2013). Although very few studies have been conducted analyzing the roles of the MAPK signaling pathways in the ovary of the laying hen, it has previously been reported that ERK1/2 acts as a negative regulator of FSH-induced signaling and in part, maintains granulosa cells of prehierarchal follicles in an undifferentiated state (Woods & Johnson 2005, Johnson 2015, Johnson & Lee 2016). Based on our findings, it is likely that metformin treatment could contribute to restricting precocious maturation of prehierarchal follicles by maintaining the cells in a quiescent state. The anti-ERK1/2 antibody and the anti-pERK1/2 antibody used in the present study are expected to detect both ERK1,

ERK2, and pERK1, pERK2, respectively. It is intriguing to note that our data suggest that ERK 1 (44 kDa) may be expressed in addition to ERK 2 (42 kDa) in the chicken granulosa cells. However, we found that anti-pERK1/2 antibody detects only pERK2 band. This is potentially due to poor or no cross-reactivity of the human anti-pERK1/2 antibody to detect chicken pERK1. Previous reports have suggested that the ERK1 gene may have been lost in the chicken due to its absence in sequenced chicken genome (Lefloch *et al.* 2008) and the absence of ERK1 protein in chicken brain protein extracts (Buscà *et al.* 2015). Furthermore, the chicken genome assemblies are still incomplete due to technical difficulties imposed by the existence of highly stable secondary gene structures (Beauchair *et al.* 2019). Further studies are required to determine the existence of the ERK1 gene in chickens.

Similar to the effects of metformin on the phosphorylation of ERK1/2, we found that metformin decreases the phosphorylation of Akt in a dose-dependent manner. Our results deviate from previous reports suggesting that metformin does not affect

Figure 7 (A–C) Effect of metformin on *CYP11A1* mRNA abundance in granulosa cells. Granulosa cells from prehierarchal follicles (3–5 and 6–8 mm) to preovulatory follicles (9–12 mm) were dispersed into single-cell suspension and treated with 0, 1, 10, or 20 mM metformin for 180 min in the presence or absence of rhFSH (10 ng/mL) at 41°C. Control received no rhFSH and no metformin treatments. Total RNA was extracted and subjected to quantitative real-time PCR as described in Fig. 5 legend. Data were standardized to *RPL19* mRNA and expressed as fold-difference vs control. ^{A,B,C,D}*P* < 0.001; *n* = 4 replicates of four broiler breeder hens each. *Inset*: Photograph of prehierarchal follicles and the most-recently recruited preovulatory follicle to denote the source of granulosa cell (*open box*).

Figure 8 (A–C) Effect of metformin on *HSD3B1* mRNA abundance in granulosa cells. Granulosa cells from prehierarchal follicles (3–5 and 6–8 mm) to preovulatory follicles (9–12 mm) were dispersed into single-cell suspension and treated with 0, 1, 10, or 20 mM metformin for 180 min in the presence or absence of rhFSH (10 ng/mL) at 41°C. Control received no rhFSH and no metformin treatments. Total RNA was extracted and subjected to quantitative real-time PCR as described in Fig. 5 legend. Data were standardized to *RPL19* mRNA and expressed as fold-difference vs control. ^{A,B,C}*P* < 0.001; *n* = 4 replicates of four broiler breeder hens each. *Inset*: Photograph of prehierarchal follicles and the most-recently recruited preovulatory follicle to denote the source of granulosa cell (*open box*).

phosphorylation of Akt in bovine granulosa cells (Tosca *et al.* 2007). Such discordance in data may possibly due to differences in the species studied. There is evidence to support that PI3K/Akt signaling is critical for the maintenance of the preovulatory follicle granulosa layer as inhibitors of PI3K were found to induce apoptosis (Johnson *et al.* 2001). Similar to chicken granulosa cells, the survival of porcine granulosa cells depend on Akt signaling pathway (Westfall *et al.* 2000). In addition, activation of the PI3K/Akt signaling pathway is associated with increased steroidogenesis in rat ovarian granulosa cells (Chen *et al.* 2007), and in bovine theca cells (Fukuda *et al.* 2009). Based on the foregoing, it is probable that the metformin-induced decrease in the phosphorylation of Akt is potentially related to the decrease in steroidogenesis observed in the present study.

We observed that treatment with metformin decreased the expression of some of the genes related to progesterone biosynthesis, including *FSHR*, *STAR*, *CYP11A1*, and *HSD3B*. Our data are in agreement with previous studies using human, rat, and bovine granulosa cells (Vrbikova *et al.* 2001, Mansfield *et al.* 2003, Tosca *et al.* 2006, 2007). Consistent with the gene expression data, we found that metformin treatment decreases progesterone production in a dose- and time-dependent manner in granulosa cells isolated from both prehierarchal (6–8 mm) and preovulatory (9–12 mm and F5) follicles. Considering the above, it is important

to determine the effect of metformin on the abundance of *STAR*, *CYP11A1*, and *HSD3B* at the protein level to confirm the decrease in progesterone secretion as observed in this study. Metformin treatment decreases progesterone and estradiol secretion from bovine granulosa cells in a dose-dependent manner (Tosca *et al.* 2007). The observed decrease in progesterone secretion in response to metformin treatment is aligned with a decrease in the abundance of pERK and pAkt and a decrease in expression of the genes related to steroidogenesis. Consistent with our *in vitro* data using granulosa cells, treatment of 6-week-old chickens with metformin for 3 weeks resulted in a 50% decrease circulating levels of testosterone and reduction in testicular weight despite no change observed in pERK or pAkt (Faure *et al.* 2016). In the present study, we found that granulosa cells from prehierarchal follicles of broiler breeder hens do secrete progesterone in response to rhFSH stimulation, albeit, requiring sustained stimulation for 72 h. In contrast, granulosa cells obtained from 6 to 8 mm prehierarchal follicles leghorn chickens were previously reported to be incompetent to produce progesterone and did not respond to ovine LH, ovine FSH, 8-bromo-cyclic AMP or 25-hydroxycholesterol (Tilly *et al.* 1991, Kim & Johnson 2018). However, more recent studies have reported low, but detectable, levels of progesterone in the media of cultured undifferentiated leghorn chicken granulosa cells stimulated with rhFSH (Johnson *et al.* 2001, Ghanem *et al.* 2019). It is possible

Figure 9 (A–I) Effect of metformin on progesterone production in cultured granulosa cells. Granulosa cells from prehierarchal follicles (6–8 mm), the most recently recruited preovulatory follicle (9–12 mm) and the smallest preovulatory follicle (F5/6) were cultured and treated with 0, 1, 10 or 20 mM metformin for 24, 48 or 72 h in the presence or absence of rhFSH (100 ng/mL) at 37°C. Progesterone concentrations in the cell culture media were quantified by enzyme-linked immunosorbent assay, as described in the 'Materials and methods' section. Progesterone quantity was normalized to the total protein concentrations in the granulosa cell lysate and analyzed. Control received no rhFSH and no metformin treatments. ^{A,B} $P < 0.05$; $n = 4$ replicate incubations of four broiler breeder hens each. *Inset*: Photograph of prehierarchal follicles and the most-recently recruited preovulatory follicle to denote the source of granulosa cell (*open box*).

that isolated granulosa cells may begin the process of differentiation during culture, possibly due to the release from inhibitory influences that exist in vivo. Alternatively, leghorn chickens, as opposed to broiler breeder hens, seldom suffer from excessive recruitment of ovarian follicles and may have a different response to rhFSH. Based on the foregoing, it is likely that sustained stimulation of granulosa cells in prehierarchical follicles by endogenous FSH may underlie excessive recruitment of follicles in broiler breeder hens.

Whereas the exact mechanisms underlying ovarian dysfunction in broiler breeder hens still remain elusive, a pharmacological intervention that corrects the ovarian disorder could increase fertile egg production from broiler breeder hens. Given the beneficial effects of metformin in correcting PCOS in human subjects, a potential role of metformin administration in treating ovarian dysfunction in broiler breeder hens is yet to be determined. While the systemic effects of long term oral administration of metformin to chickens are currently unknown, intravenous bolus injection of metformin daily for 2 weeks to leghorn chickens was associated with a significant decrease in the levels of plasma triglycerides, cholesterol, insulin, as well as a significant decrease in egg production (Chen *et al.* 2011). Metformin, a drug of choice for treating type 2 diabetes and PCOS is typically administered orally for several months to years. Furthermore, the pharmacokinetics of metformin administered orally vs intravenously differs significantly, and therefore, the biological effects of metformin on reproductive system could be very different following the two routes of administration. As orally administered metformin is bioactive in chickens (Ashwell & McMurtry 2003, Sato *et al.* 2011), long term dietary supplementation of metformin to broiler breeder hens is necessary to determine its effects on egg production, fertility and hatchability.

In summary, we provide evidence that metformin decreases progesterone secretion from granulosa cells isolated from broiler breeder hen prehierarchical and preovulatory follicles. Such a decrease in steroidogenesis was found to be associated with the inhibition of ERK2 and Akt signaling pathways and a decrease in the expression of related genes. Our data suggest that metformin has the potential to affect recruitment and maturation of prehierarchical and preovulatory follicles in the broiler breeder hen ovary. Future investigations should be directed toward determining the extent to which metformin could ameliorate ovarian dysfunction and improve fertile egg production in broiler breeder hens.
