Summary. The specific activity of the type I and type II isoenzyme forms of the cAMP-dependent protein kinase (EC 2.7.1.37) in the caput epididymidis of the intact rat was less than that of the caudal region while the isoenzyme ratio (type II:type I) of the former was greater than that of the latter, with type II being the predominant form in both regions. By 7 days after castration, the specific activities in both regions had decreased to the same level. The isoenzyme ratio of the caudal region increased to that of the caput region which remained unchanged after castration. The change in the isoenzyme ratio in the caudal region was mainly due to loss of the type I isoenzyme. The castration effects were reversed by testosterone administration.

Introduction

The importance of the epididymis in sperm maturation and hence male fertility has attracted much attention for a long time (for review, see Mann & Lutwak-Mann, 1981). Androgens appear to control epididymal functions by regulating several biochemical and physiological processes (for review, see Brooks, 1981). However, limited studies have been reported on protein phosphorylation in the epididymis even though this important regulatory mechanism, catalysed by protein kinases, has been extensively investigated in other tissues (Greengard, 1978; Carlson, Bechtel & Graves, 1979; Glass & Krebs, 1980; Walter & Greengard, 1981; Cohen, 1982; Sharma, 1982). Epididymal protein phosphorylation has been shown to depend on testosterone (Kadohama & Turkington, 1974). There appear to be 3 forms of protein kinase in rat epididymal tissue extracts: cyclic AMP-dependent, cyclic AMP-independent and cyclic GMP-dependent. Activities of the cyclic AMP-dependent and -independent protein kinases of the caput epididymidis from immature rats are elevated after testosterone administration (Bernard & Wassermann, 1972) and the ratio of the cyclic AMP-dependent to the cyclic GMP-dependent protein kinases increases during postnatal development (Kuo & Williams, 1979). As in other tissues, the cyclic AMP-dependent protein kinase of the rat epididymis also exists as two isoenzymes, types I and II (Biswa & Majumder, 1982). The isoenzymes differ in charge and can be separated by ion-exchange chromatography. We have now examined the effect of androgen on the two isoenzymes of the cyclic AMP-dependent protein kinase from the caput and the cauda regions of the rat epididymis.

Materials and Methods

Adult albino Fischer rats weighing 250–300 g were divided into four groups: intact control, castrated, castrated with testosterone treatment and castrated with oil (vehicle) treatment. Castration was performed by the scrotal route under pentobarbitone sodium anaesthesia (5 mg
Nembutal/100 g body weight). Testosterone was administered by daily subcutaneous injection of testosterone propionate (Schering A.G., Berlin/Bergkamen, West Germany) dissolved in safflower oil (Hain Pure Food Co., Los Angeles, U.S.A.) at a dose of 1 mg/kg body weight. During the experiment, all rats were maintained on normal diet and water under a daily cycle of 13-h light and 11-h darkness.

Seven days after castration, each epididymis was surgically removed from rats under ether anaesthesia. The epididymis was dissected free from fat and divided into the caput and cauda region. They were washed twice in Hank's balanced salt solution (HBSS), containing 0.138 M-NaCl, 4.17 mM-NaHCO	extsubscript{3}, 0.3 mM-Na	extsubscript{2}HPO	extsubscript{4}, 5.4 mM-KCl, 0.4 mM-KH	extsubscript{2}PO	extsubscript{4}, 1.26 mM-CaCl	extsubscript{2}, 0.49 mM-MgCl	extsubscript{2}, 0.8 mM-MgSO	extsubscript{4}, and 5.6 mM-glucose, pH 7.4, blotted dry and weighed. Pooled caput or cauda epididymal segments were chopped into small pieces in the medium using a pair of scissors. The spermatozoa were released by gentle passage into and out of a Pasteur pipette. The tissue pieces were allowed to settle and the supernatant fluid was discarded. The tissue pieces were then resuspended in HBSS and centrifuged through a layer of 3% Ficoll in 0-9% (w/v) NaCl at 35 g for 5 min. The final pellet was resuspended in HBSS. The above procedure was carried out at 4°C. The contamination by spermatozoa in the washed tissue was determined using a haemocytometer and was <5% of the total spermatozoa in the initial fluid. Parts of the washed tissue were fixed in Bouin's fluid, embedded in paraffin wax and stained with haematoxylin-eosin; phase-contrast microscopy showed the normal appearance of the cuboidal epithelial cells.

The rest of the washed tissue was homogenized in 1-2 volumes of 0-25 M-sucrose in 50 mM-Tris-HCl, pH 7-4, with a Teflon-to-glass homogenizer at 4°C. The homogenate was centrifuged at 27 000 g for 15 min at 4°C. Only the supernatant fluid was used as the source of the enzyme.

Protein kinase activity was assayed at 37°C according to the method of Reddi, Ewing & Williams-Ashman (1971). The assay mixture (125 μl) contained 375 μg salmon protamine (Sigma, St Louis, Missouri, U.S.A.), 10 mM-MgCl	extsubscript{2}, 1 mM-EDTA, 10 mM-NaF, 10 mM-β-mercaptoprotoanol, 2 mM-theophylline, 1 mM-[γ-32P]ATP (5 × 10⁴ c.p.m./nmol), 10 μM-cAMP, 10 mM-Tris-HCl, pH 6-5, and an appropriate amount of epididymal homogenate. Homogenate preheated at 80°C for 10 min was used as the assay control. In these conditions, the product formation was linear with incubation time up to 10 min.

[γ-32P]ATP was prepared from 32Pi (sp. act. 10 mCi/ml; Radiochemical Centre, Amersham, U.K.) as described by Glynn & Chappell (1964).

Before loading onto a DEAE-cellulose column (1.2 × 7 cm), the homogenate was dialysed against 50 volumes of 10 mM-potassium phosphate buffer, pH 7-0, for 3 h at 4°C. The column was equilibrated with the phosphate buffer and eluted with a linear gradient of 10 to 500 mM-potassium phosphate buffer, pH 7-0. In all cases, the column recovery was 95-130% of the applied protein kinase activity.

**Results**

**Protein kinase activity of the epididymal tubules**

It was established that the homogenization yielded about 80% of the total protein kinase activity in the soluble fraction and the remainder was associated with the pellet fraction. The specific activity of the soluble protein kinases of the cauda epididymal tubule was significantly (P < 0.001) greater than that of the caput epididymidis (Table 1). However, androgen-deprivation by castration for 7 days depressed the enzyme activity in both parts of the tubules to approximately the same level, and about one-third and one-half of the enzyme activity was lost from the caput and the cauda tubules respectively. Administration of testosterone restored the activity to 75-80% of the intact control values. Administration of the vehicle, safflower oil, had no restorative effect. The epididymal weight decreased by half in 7 days after castration but was maintained by the administration of testosterone.

Protein kinase isoenzymes

Although a small column (1.2 x 7 cm) of DEAE-cellulose was used, it was still necessary to pool soluble fractions from 3 (intact) or 7 (castrated) rats. To facilitate comparison between the enzyme profiles from intact control and castrated rats, approximately equal activities of the material from both groups were separately applied to the same column.

Protein kinase activity of the caput or cauda epididymidis was clearly resolved into two isoenzymes, type I being eluted from the column at 50-75 mM-potassium phosphate and type II being eluted at 180-210 mM (Text-fig. 1). The resolution capacity of the column was prechecked.

Text-fig. 1. Activity profiles of protein kinases from the (a) caput and (b) cauda epididymidis of intact and castrated rats. Isoenzyme types I and II were resolved in a DEAE-cellulose column (1.2 x 7 cm), eluted with a phosphate buffer gradient. The total activities applied to the column were (a) 7.2 and 9.8 and (b) 15.6 and 12.4 nmol $^{32}$P incorporated/min from the epididymis of intact and castrated rats respectively. The phosphate gradient is represented by the straight line without symbols.
with testicular protein kinase prepared according to Lee, Radloff, Schwegge & Jungman (1976); protein kinase I of this preparation was eluted at 80 mM-potassium phosphate and type II at 210 mM (data not shown). The salt concentrations agreed with the reported values (Lee et al., 1976).

Protein kinase II was the predominant form in the epididymal tubules; protein kinase I was a minor fraction in the caput region but its concentration was greater in the caudal part. If the activity profile was divided at the trough between two peaks, the approximate ratio between type II and type I isoenzymes can be estimated. From three preparations, the isoenzyme ratios (type II:type I) were 3:4 ± 1:0 and 2:5 ± 0:5 for the caput and the cauda epididymidis respectively. By 7 days after castration, the caput epididymidis showed no change in the activity profile (Text-fig. 1a) or in the isoenzyme ratio (3:9 ± 0:4, n = 3). In the cauda epididymidis the type I isoenzyme was much more depressed than type II (Text-fig. 1b) and the ratio increased significantly (P < 0:001) to 4:1 ± 0:8 (n = 3). In fact, the activity profile of each region of the epididymis from the castrated rats appeared similar to that of the normal caput epididymidis (Text-fig. 1). The isoenzymes from the castrated rats were eluted at salt concentrations slightly lower than those of the normal rats, but this was not consistently seen among the 3 preparations.

In a preliminary study, 10 μM-cAMP stimulated type I isoenzyme of the normal caput epididymidis to 80% but did not affect that of the caudal region. Under the same conditions, type II isoenzyme from either region of the normal epididymis was stimulated up to 30%.

Discussion

Since protein kinases are also present in the epididymal fluid and spermatozoa (Garbers, First & Lardy, 1973; Hoskins, Stephens & Hall, 1974; Lee & Iverson, 1976; De-eknamkul, 1980; Majumder, 1981), it is essential to wash the chopped tubules before release of the tubular protein kinases by homogenization. For this reason, the results of the present study should not have been affected by contamination by epididymal fluid and spermatozoa, and should therefore be more accurate than those using unwashed tubules (Bernard & Wassermann, 1972; Kuo & Williams, 1979).

Our finding of a difference in the specific activity of protein kinase (Table 1) between the caput and the cauda epididymidis clearly extends the list of enzymes with differential activities along the epididymis (Brooks, 1981). However, protein kinase is the first enzyme so far studied that shows regional difference in the isoenzyme composition (Text-fig. 1). The importance of these regional differences is still unknown but they could be related to the differential phosphorylation of acidic chromatin proteins observed in the two parts of the epididymis (Kadohama & Turkington, 1974).

Like several other epididymal enzymes, the protein kinase activity is androgen-dependent since its activity decreases after castration but is maintained by testosterone administration (Table 1). Although both isoenzymes of the caput region are equally sensitive to androgen withdrawal (Text-fig. 1a), the high sensitivity to androgen withdrawal of the protein kinase I of the cauda epididymidis (Text-fig. 1b) is similar to that observed in two other steroid-sensitive tissues, the ventral prostate and levator ani muscle (Fuller, Byus & Russell, 1978). The importance of specific regulation of the type I isoenzyme in the cauda epididymidis by testosterone must await further study on its cellular location and its phosphorylation products. Nevertheless, the column recovery is high and its variations cannot be correlated with the observed loss of the type I isoenzyme.

With protamine as substrate, cAMP does not stimulate the unfractionated protein kinases from rat epididymis (Bernard & Wassermann, 1972). So the presence of a cAMP-dependent form cannot be determined by the data in Table 1. However, a study by Biswas & Majumder (1982) and our preliminary observations on the fractionated enzymes suggest that each isoenzyme in Text-fig. 1 is a mixture of both cAMP-dependent and -independent forms. Further work will be needed to establish the relationship between these two forms.
